Observations of stellar remnants are reasonably in accord with the above picture. White dwarfs slowly cooling to the same temperature as the universe (3 K) seem to account for most of the dying stars, which is consistent with the fact that most stars are born with relatively low masses. At the sites of some historical supernova explosions, astronomers have found objects called pulsars, which are thought to be rotating magnetized neutron stars. And in some close binary systems, where a normal star is transferring matter to a compact companion, the companion can be inferred in different situations to be a white dwarf, a neutron star, or a black hole.

Pulsars

The evolution of stars. Whenever nuclear fuel runs out in the central regions of a star (*e.g.,* when hydrogen becomes exhausted at the end of the main-sequence stage of stellar evolution), the core must contract and heat up. This increases the flow of energy to the outside, which accelerates evolution. A shell of material outside the contracting core may become hot enough to trigger thermonuclear fusion, and eventually the central temperature also may rise enough to ignite what was previously nuclear ash into new fuel. The entire process will then repeat. Thus, core fusion of hydrogen into helium can give way to shell hydrogen fusion. This can be followed by helium ignition in the core, with the star now possessing a shell of hydrogen fusing into helium and a core of helium fusing (with itself twice) into carbon. If the temperature rises sufficiently, the carbon can also capture a helium nucleus to become oxygen. Helium exhaustion in the core is followed by helium fusing in a shell and hydrogen fusing in another shell above that. Then, core ignition involving carbon or oxygen fusing with themselves can yield a variety of still heavier elements. The layered shell structure and the chain of possible reactions become more and more complicated, generating along the way such common elements as silicon, sulfur, and calcium, but the process cannot proceed forever. Eventually, if nothing else intervenes, iron will be created. The nucleus of the iron atom is the most bound of all atomic nuclei; it is not possible to release nuclear energy by adding nucleons (*i.e.,* protons and/or neutrons) to iron (or subtracting them). Hence, if iron is created, as in the cores of the more massive stars, the star must come to a catastrophic end because it will continue to lose heat to its surroundings. What happens in computer simulations of this event is that the core of the star implodes, forming a large mass of hot neutrons at temperatures and densities considerably in excess of 10^9 K and 10^{14} g/cm^3 (grams per cubic centimetre). Under such

Production of iron

conditions, huge numbers of neutrinos are released, and these elementary particles appear capable of depositing enough energy into the extremely dense infalling envelope of the star to drive an outwardly propagating shock wave that expels the envelope in a supernova explosion. In this way a wide variety of the nuclear products of stellar evolution can be introduced into the interstellar medium to enrich the general elemental mix. From this point of view, it is encouraging that, apart from hydrogen and helium, elements that are bountiful in the natural environment (and in living species)—carbon, nitrogen, oxygen, silicon, sulfur, calcium, iron, etc.—also lie on the main line of stellar nucleosynthesis.

The prediction that supernova explosions should liberate huge quantities of neutrinos found confirmation in the sudden brightening in 1987 of a previously known star in the Large Magellanic Cloud. The appearance of Supernova 1987A (SN 1987A), as this object was called, coincided with a burst of neutrino emission recorded by high-energy physics experiments originally designed to detect proton decay (see below). The magnitude and timing of the neutrino burst fit well with the model of the iron-core collapse of a star whose mass on the main sequence amounted to about 20 solar masses. Subsequent measurements of the light curve demonstrated that, in general agreement with nucleosynthetic expectations, SN 1987A ejected about 0.07 solar mass of the radioactive isotope nickel-56, with a half-life of 6 days, which decays into cobalt-56, with a 77-day half-life, and then into stable iron-56.

Another interesting by-product of the supernova mechanism described above is that large numbers of free neutrons can be liberated in the envelope. Seed nuclei can capture these free neutrons to become heavier and eventually create many of the elements beyond iron in the periodic table, including radioactive species like uranium. Different isotopes of uranium decay at different rates, and knowing the primitive ratios in which supernovas create these isotopes enables radiochemists to compute, from the corresponding measured values in uranium ore, the elapsed time since these isotopes were produced and introduced into the solar system. Depending on the rates of supernova explosions in the history of the Galaxy, these calculations indicate that uranium synthesis began between 6×10^9 and 1.5×10^{10} years ago. This, then, is another method for independently estimating the age of the Galaxy. Again, within the uncertainties of the determination, the value is consistent with the Hubble expansion age (see *The extragalactic distance scale and Hubble's constant*).

The fundamental difference in evolutionary outcomes between high-mass and low-mass stars can be traced to the theory of white dwarfs. Basically, every star eventually tries to generate a white dwarf at its core as it evolves and undergoes core contraction. During the 1920s, with the dawn of modern quantum mechanics, the British physicist Ralph H. Fowler showed that a white dwarf has the peculiar property that the more massive it is, the smaller its radius. The reason is relatively simple: a more massive white dwarf has more self-gravity, and so more pressure is required to counter the stronger gravity. Pressure increases when the degenerate electron gas constituting a white dwarf is compressed; it becomes strong enough to balance gravitational force only at very great densities. Consequently, equilibrium between the internal degeneracy pressure and the force of gravity is reached at a smaller size for a more massive white dwarf.

The Chandrasekhar limit

The American astrophysicist Subrahmanyan Chandrasekhar made a crucial modification to this hypothesis in order to accommodate Einstein's special theory of relativity. Chandrasekhar showed that relativistic effects imposed an upper limit on the mass of possible white dwarfs. This limit arises because electrons cannot move faster than the speed of light; there comes a point where the increase in internal degeneracy pressure is no longer able to keep the self-gravity from literally trying to crush the star to zero size. For likely white-dwarf compositions, this limit corresponds to 1.4 solar masses as noted above.

Consider a star that attempts to exceed the Chandrasekhar limit, assuming that it has enough material—even after envelope-mass loss—to try to build a massive white dwarf by depositing layer after layer of nuclear ash into its core. As the limit is approached, the core's outer boundary shrinks almost to arbitrarily small dimensions, generating above it enormous gravitational fields. To counteract the gravity, the pressures in the shell above the core must rise correspondingly, yielding densities and temperatures that are as high as needed to drive all thermonuclear reactions to completion. If nothing else intervenes, this situation must end in the iron catastrophe described above.

In contrast, in a low-mass star the final mass of the core may end up well below the Chandrasekhar limit. The shells outside the core may still become dense and hot enough to yield copious amounts of hydrogen and helium fusion, and this heat input into the envelope will greatly distend the envelope of the star, bringing the star to the red giant and red supergiant evolutionary phases that characterize the later stages. The outer atmospheres of such stars are often cool enough to allow the condensation of some of the heavy elements into solid particles. Dust grains composed of a rocky silicate are probably the most common outcome, but graphite or silicon carbide grains are possibilities in carbon-rich stars. In any case, because the envelope of the star is so extended, the surface gravity is too weak to hold the atmospheric mix of gas and dust, and this mixture blows out of the star as a prodigious stellar wind. Objects in this state are called planetary nebulas. The observed loss of matter occurs at a rate rapid enough to strip off the entire envelope, revealing eventually a white-hot core that is now a bare white dwarf. Since the mass loss reduced the stellar mass below the Chandrasekhar limit, the core never progressed to very advanced stages of nuclear fusion, giving the most common white dwarfs in the Galaxy a likely composition of carbon and oxygen.

Red giant and red supergiant phases

Interstellar clouds. Observations conducted at radio, infrared, and optical wavelengths show that the majority of stars are formed from giant clouds of gas and dust that exist in interstellar space. There are three basic varieties of clouds that astronomers distinguish on the basis of the dominant physical state in which the hydrogen gas is found: atomic, molecular, or ionized. Hydrogen is singled out in the classification scheme because of its preeminent abundance in the Cosmos.

Atomic, molecular, and ionized hydrogen clouds

Atomic hydrogen clouds are the most widely distributed in interstellar space and, together with molecular hydrogen clouds, contain most of the gaseous and particulate matter of interstellar space. Molecular hydrogen clouds contain a wide range of molecules besides the hydrogen molecule H_2 and for that reason are simply called molecular clouds. Ionized hydrogen clouds, called H II regions by astronomers, are fluorescent masses of gas, such as the famous Orion Nebula, which have been lit up by hot blue stars recently born from the neutral gas, the hydrogen becoming dissociated and ionized because of the copious outpouring of ultraviolet photons from such massive stars.

Dust particles are suspended in all three types of clouds, and their effects can be seen in the absorption and scattering of optical light or in the thermal emission of infrared radiation. The refractory cores of the dust grains were probably expelled from the atmospheres of countless red giant stars, although icy mantles may be acquired in molecular clouds by the adhesion of molecules to the cold grain surfaces when they collide. It has been estimated that dust grains typically account for 1 percent of the mass of an interstellar cloud. Because the internal constitution of dust is primarily elements heavier than hydrogen and helium and because the cosmic mass fraction of all such elements is only a few percent of the total, dust grains must contain a significant fraction of the total cosmic abundance of heavy elements. This deduction is in accord with the observational finding that many heavy elements are severely underrepresented in the gas phase of interstellar clouds. They presumably have condensed out as solid particles.

Primary sites of star formation

Of greatest interest to the present discussion are the molecular clouds, because it is from giant complexes of such clouds that most stars are formed. Radiative cooling by the molecules and dust in them keeps the matter at very low average temperatures, about 10 K, and at relatively

high densities as compared with atomic hydrogen clouds. These two circumstances, combined with the large mass (10^5 or 10^6 solar masses) of a typical giant molecular cloud complex, make molecular clouds ideal sites for star formation because, even with dimensions spanning hundreds of light-years, they are held together by their self-gravitation. Once a gaseous astronomical body becomes self-gravitating, the formation of still more condensed states—in this case, stars—is almost inevitable.

Star formation. Detailed radio maps of nearby molecular clouds reveal that they are clumpy, with regions containing a wide range of densities—from a few tens of molecules (mostly hydrogen) per cubic centimetre to more than one million. Stars form only from the densest regions, termed cloud cores, though they need not lie at the geometric centre of the cloud. Large cores (which probably contain subcondensations) up to a few light-years in size seem to give rise to unbound associations of very massive stars (called OB associations after the spectral type of their most prominent members, O and B stars) or to bound clusters of less massive stars. Whether a stellar group materializes as an association or a cluster seems to depend on the efficiency of star formation. If only a small fraction of the matter goes into making stars, the rest being blown away in winds or expanding H II regions, then the remaining stars end up in a gravitationally unbound association, dispersed in a single crossing time (diameter divided by velocity) by the random motions of the formed stars. On the other hand, if 30 percent or more of the mass of the cloud core goes into making stars, then the formed stars will remain bound to one another, and the ejection of stars by random gravitational encounters between cluster members will take many crossing times.

Low-mass stars also are formed in associations called T associations after the prototypical stars found in such groups, T Tauri stars. The stars of a T association form from loose aggregates of small molecular cloud cores a few tenths of a light-year in size that are randomly distributed through a larger region of lower average density. The formation of stars in associations is the most common outcome; bound clusters account for only about 1 to 10 percent of all star births. The overall efficiency of star formation in associations is quite small. Typically less than 1 percent of the mass of a molecular cloud becomes stars in one crossing time of the molecular cloud (about 5×10^6 years). Low efficiency of star formation presumably explains why any interstellar gas remains in the Galaxy after 10^{10} years of evolution. Star formation at the present time must be a mere trickle of the torrent that occurred when the Galaxy was young.

A typical cloud core rotates fairly slowly, and its distribution of mass is strongly concentrated toward the centre. The slow rotation rate is probably attributable to the braking action of magnetic fields that thread through the core and its envelope. This magnetic braking forces the core to rotate at nearly the same angular speed as the envelope as long as the core does not go into dynamic collapse. Such braking is an important process because it assures a source of matter of relatively low angular momentum (by the standards of the interstellar medium) for the formation of stars and planetary systems. It also has been proposed that magnetic fields play an important role in the very separation of the cores from their envelopes. The proposal involves the slippage of the neutral component of a lightly ionized gas under the action of the self-gravity of the matter past the charged particles suspended in a background magnetic field. This slow slippage would provide the theoretical explanation for the observed low overall efficiency of star formation in molecular clouds.

The effects of magnetic fields

At some point in the course of the evolution of a molecular cloud, one or more of its cores become unstable and subject to gravitational collapse. Good arguments exist that the central regions should collapse first, producing a condensed protostar whose contraction is halted by the large buildup of thermal pressure when radiation can no longer escape from the interior to keep the (now opaque) body relatively cool. The protostar, which initially has a mass not much larger than Jupiter, continues to grow by accretion as more and more overlying material falls on top of it. The infall shock, at the surfaces of the protostar and the swirling nebular disk surrounding it, arrests the inflow, creating an intense radiation field that tries to work its way out of the infalling envelope of gas and dust. The photons, having optical wavelengths, are degraded into longer wavelengths by dust absorption and reemission, so that the protostar is apparent to a distant observer only as an infrared object. Provided that proper account is taken of the effects of rotation and magnetic field, this theoretical picture correlates with the radiative spectra emitted by many candidate protostars discovered near the centres of molecular cloud cores.

An interesting speculation concerning the mechanism that ends the infall phase exists: it notes that the inflow process cannot run to completion. Since molecular clouds as a whole contain much more mass than what goes into each generation of stars, the depletion of the available raw material is not what stops the accretion flow. A rather different picture is revealed by observations at radio, optical, and X-ray wavelengths. All newly born stars are highly active, blowing powerful winds that clear the surrounding regions of the infalling gas and dust. It is apparently this wind that reverses the accretion flow.

The geometric form taken by the outflow is intriguing. Jets of matter seem to squirt in opposite directions along the rotational poles of the star (or disk) that sweep up the ambient matter in two lobes of outwardly moving molecular gas—the so-called bipolar flows. Such jets and bipolar flows are doubly interesting because their counterparts were discovered some time earlier on a fantastically larger scale in the double-lobed forms of extragalactic radio sources (see below *Quasars and related objects*).

Bipolar flows

The underlying energy source that drives the outflow is unknown. Promising mechanisms invoke tapping the rotational energy stored in either the newly formed star or the inner parts of its nebular disk. There exist theories suggesting that strong magnetic fields coupled with rapid rotation act as whirling rotary blades to fling out the nearby gas. Eventual collimation of the outflow toward the rotation axes appears to be a generic feature of many proposed models.

Pre-main-sequence stars of low mass first appear as visible objects, T Tauri stars, with sizes that are several times their ultimate main-sequence sizes. They subsequently contract on a time scale of tens of millions of years, the main source of radiant energy in this phase being the release of gravitational energy. When their central temperatures reach values comparable to 10^7 K, hydrogen fusion ignites in their cores, and they settle down to long stable lives on the main sequence. The early evolution of high-mass stars is similar; the only difference is that their faster overall evolution may allow them to reach the main sequence while they are still enshrouded in the cocoon of gas and dust from which they formed.

GALAXIES

Astronomers have found that most of the matter in the universe is concentrated in galaxies. Paradoxically, they also have discovered from studying galaxies that the universe may contain large quantities of mass that does not emit any light. There are some hints that this hidden mass, or dark matter, may not even be in the form of ordinary material. The discrepancy between the mass that can be seen in galaxies and the mass needed to account for their gravitational binding has become one of the foremost unsolved problems in modern astrophysics.

The Milky Way Galaxy. Any discussion of galaxies should begin with the local system, where the wealth of information is greatest. The Galaxy contains three main structural components: (1) a thin flat disk of stars, gas, and dust, (2) a spheroidal central bulge containing only stars, and (3) a quasi-spherical halo of old stars. The Sun is found in the first component, while globular clusters are found in the third. The nucleus of the Galaxy lies at the centre of all three components, but it cannot be seen optically from the solar system because of the thick tracts of dust that lie in the disk between it and the galactic centre, obscuring the view. The nucleus can be probed at radio, infrared, X-ray, and gamma-ray wavelengths; a descrip-

tion of these findings is provided below in a more general discussion of the activity witnessed in galactic nuclei.

Distribution of stellar populations in the Galaxy

A hint of the processes of the formation and evolution of the Galaxy is contained in the general correlation between the spatial location of a star in the galactic system and its heavy-element abundance. The stars found in the disk of the Galaxy are mostly Population I stars; those in the halo are of the Population II type; and those in the bulge are a mixture of the two. This correlation was first noticed in the 1940s by the American astronomer Walter Baade from his investigation of the Andromeda galaxy. Since the theory of nucleosynthesis states that the abundance of heavy elements in successive generations of stars should increase with age, it can be deduced that star formation in the halo terminated long ago, while it has continued in the disk to the present day.

The shapes acquired by the different stellar components can be understood in terms of the orbital characteristics of the different stellar populations. For Population I stars, the motion corresponds nearly to circular orbits in a single plane; the random velocities above the circular component are small, accounting for the flattened shape of the galactic disk. For Population II stars, the noncircular velocities are much larger; the stars orbit randomly about the Galaxy like a swarm of bees around a hive, accounting for the spheroidal shapes of the galactic bulge and halo.

In 1962 Olin Eggen of Australia, Donald Lynden-Bell of England, and Allan Sandage of the United States pieced together the chemical and kinematic lines of evidence to argue that the Galaxy must have originated through the coherent dynamic collapse of a single large gas cloud, in which the stars of the halo condensed quickly (within about 2×10^8 years) from the gas, to be followed by the formation of the bulge and disk. Subsequent discoveries that the globular clusters of the halo have a spread of heavy-element abundances and probable ages and that some stars in the bulge are as old or older than the oldest stars in the halo have cast doubt on this simple view. An alternative scenario pictures the Galaxy to have built up relatively slowly over a period of a few times 10^9 years through the agglomeration of smaller galactic fragments. Some astronomers believe that a "thick-disk" component reported for the Milky Way system and other galaxies arise by this process, but too great a thickening of the layer of stars in the disk may result if the captured companions have more than about 10 percent of the Galaxy's mass.

Although the velocities of the stars within a few thousand light-years of the Sun in the direction perpendicular to the galactic plane are generally small, they are not zero. By investigating the statistics of these motions and the vertical structure of the disk, it is possible to deduce the vertical component of the gravitational field of the Galaxy and thereby the total mass of material required locally to supply the observed gravity. The quantity of required material is called Oort's limit (after the aforementioned J.H. Oort), and it exceeds by a factor of about two the quantity of available material, as observed in the form of known stars and gas clouds. This result constitutes the closest example of a general discrepancy arising on galactic scales whenever dynamically derived masses are compared with direct counts of observationally accessible objects. The missing matter in Oort's limit refers, however, to a flattened population and may differ in ultimate resolution from the more general dark-matter problem (see below), which is associated with the halos of galaxies and beyond.

Oort's limit

From star counts, one can derive another quantity of astronomical interest, the mean brightness (per unit area) in the solar neighbourhood. If one divides this quantity into the mass (per unit area) corresponding to Oort's limit, one obtains the local mass-to-light ratio, which astronomers have measured to be about five in solar units. In other words, the gravitating mass in the Galaxy has a mean efficiency for producing light that is five times less than the Sun's. This implies, first, that the average star must be less massive than the Sun and, second, that the amount of helium presently inside stars—in contrast with the heavier elements—cannot have been produced by stellar processes. The reason is simple. The Sun, with a mass-to-light ratio of unity, will manage to convert about 10 percent of its mass (in the core) into helium in 10^{10} years (after which it leaves the main sequence); matter with a mean mass-to-light ratio of five, therefore, would convert only 2 percent of its mass to helium in 10^{10} years, roughly the age of both the Galaxy and the universe. The cosmic abundance of helium is approximately 26 or 27 percent of the total mass; thus, unless the Galaxy was much brighter in the past than it is today (for which there is no observational evidence), the bulk of the helium in the universe must have been created by nonstellar processes. Astronomers now believe that a primordial abundance of helium of about 24 percent by mass emerged from the big bang. Among other arguments, this is the value derived from the analyses of the chemical compositions of H II regions in external galaxies where the heavy-element abundance is very low and where, therefore, nuclear processing by stars has presumably been small.

It is possible, of course, to examine the statistics of the random velocities of stars in the two directions parallel to the galactic plane as well as in the vertical direction. The Swedish astronomer Bertil Lindblad was the first to carry out such an analysis. His work, combined with Oort's study in 1927 of the constants of the differential rotation of the Galaxy, gave the period of revolution of stars such as the Sun about the galactic centre. The modern value for this period equals about 2.5×10^8 years. With Shapley's measurement of the distance to the galactic centre and with the assumption that stars like the Sun circle the Galaxy because they are gravitationally bound to it, it is possible to estimate the total mass interior to the solar distance from the galactic centre. Modern estimates yield roughly 2×10^{11} solar masses. Since the Sun is somewhat more massive than the typical star, the Galaxy must contain more than 10^{11} stars.

Distribution of mass in the Galaxy

Detailed information can be gleaned about the distribution of mass in the Galaxy if one possesses a knowledge of the rotational speeds of disk matter at other radial locations in the Galaxy. The most common measurements are of atomic hydrogen in its spin-flip transition at 21-centimetre wavelength and of the carbon monoxide molecule in one or another of its rotational transitions at millimetre wavelengths. These observations also provide data concerning the total amount of atomic and molecular hydrogen gas contained in the Galaxy. To convert the carbon monoxide abundance to a molecular hydrogen abundance (which cannot be measured directly except at ultraviolet wavelengths that suffer tremendous dust extinction) requires a complicated series of calibrations of nearby sources. The mass of gas in the Galaxy is a few times 10^9 solar masses, about evenly divided between atomic and molecular hydrogen clouds. Most of the observed mass of the Galaxy is in the form of stars; gas and dust make up only a few percent of the total.

By a combination of such measurements, astronomers can obtain the rotation curve of the Galaxy from its innermost regions to a radial distance of almost 60,000 light-years from the galactic centre. This rotation curve implies that the mass of the Galaxy measured out to a certain distance r does not converge to a fixed value as r increases but continues to rise roughly in linear proportion to r. The mass contained interior to the most distant radius measured amounts to about 5×10^{11} solar masses. Observations indicate, however, that the integrated light from a galaxy like the Milky Way system does not increase similarly with increasing r but approaches asymptotically a finite value. Thus, the local mass-to-light ratio of the Galaxy, like those of other spiral galaxies, must increase dramatically toward its outer parts where the halo dominates. Another way to state the problem is that the observed rotational velocities of gas clouds in the outer parts of spiral galaxies are so large that they would not be bound to the galaxies unless the galaxies were more massive than inferred from direct measurements of their stellar and gas contents. Most astronomers now accept the likelihood of dark halos that contain as much mass as is present in the visible disks and bulges; more controversial are the claims that these halos may increase known galactic masses by factors of 10 or 100.

Existence of dark halos

Classification of galaxies. Astronomers judge galaxies in

accordance with three criteria: morphological appearance, stellar content, and overall luminosity (see GALAXIES). Although the number of galaxies found in the universe is enormous, Edwin P. Hubble discovered that a few basic categories specify their observed shapes. Galaxies that have irregular shapes are called irregulars, denoted Irr. Irregulars are subdivided into two categories: Irr I and Irr II. Irr I galaxies have OB stars and H II regions; examples of such systems are the Large and Small Magellanic Clouds. Irr II galaxies are amorphous in texture and show no resolution into bright stars or associations, but they do contain much neutral gas and are probably forming massive numbers of stars as attested to by their blue colours. Galaxies that have regular forms are divided into two broad groups: ellipticals and disks. Elliptical galaxies, denoted E, have roundish shapes. Disk galaxies, on the other hand, have flattened shapes. They can be further divided into two subcategories: ordinary spirals, denoted S, and barred spirals, denoted SB. In addition, there exists a transition type between ellipticals and spirals, which are often called lenticulars. The lenticular galaxies are designated either S0 or SB0, depending on the absence or presence of a bar of stars, gas, and dust through the nucleus.

Ellipticals and spirals constitute the two largest reservoirs of the stars in the universe, and the placement of individual galaxies into these two major categories is refined by adding a numeral 1 through 7 or a letter "a" through "c" to their designation. The sequence E0 to E7 denotes one of increasing flattening (as seen in projection in the sky). The sequence Sa to Sc, or SBa to SBc, represents decreasing tightness of winding of the spiral arms and decreasing size of the central bulge relative to the disk.

Luminosity class

A useful analogy with stars is the introduction by Sidney van den Bergh of Canada of the concept of luminosity class. The scheme appends to the Hubble type a luminosity-class label, from Roman numeral I for the intrinsically brightest (and most massive) spiral galaxies to Roman numeral V for the intrinsically faintest (and least massive) spirals. The utility of this scheme, as applied to spirals, rests with the fact that it is possible to assign them a luminosity class without actually measuring their distance (to obtain an absolute brightness from an observed apparent brightness). The luminosity class of a spiral galaxy correlates well with the regularity (or "prettiness") of the spiral structure: in class I galaxies the arms are long and well developed and have a high surface brightness; in class III they are patchy and fuzzy; and in class V there may be barely a hint of a spiral structure. Elliptical galaxies, lacking spiral arms, cannot have their absolute brightnesses estimated by the same morphological considerations; hence, the concept of a luminosity class for them is less empirically useful. When the masses of elliptical galaxies at known distances are deduced from measured velocities or apparent luminosities, they range from a few million solar masses (dwarf ellipticals) to more than 10^{12} solar masses (giant ellipticals). Thus, giant ellipticals and giant spirals have comparable masses. Yet, it should be noted that the very largest elliptical galaxies in the universe, the supergiant cD systems, are unique and perhaps have masses approaching 10^{14} solar masses in some extreme cases.

Dynamics of ellipticals and spirals. The motions of stars in an external galaxy can be studied in a statistical sense by examining the Doppler shifts of the optical absorption lines in the integrated light along the line of sight through different parts of the object. Radio-spectroscopic observations can give similar information concerning the gaseous components of the system. Some important results from these studies are as follows.

The dominant motion in the disks of normal spiral galaxies is differential galactic rotation, with the random motions of stars being relatively small and that of the atomic and molecular gas smaller still. A surprising result is that the rotation curves of almost all well-studied spiral galaxies become flat at large radial distances. As one goes out from the centre, the rotational velocity rises to a constant value V and then maintains it for as far as one can make the measurements. This implies, as already noted for the Milky Way Galaxy, that the mass contained within r increases linearly with increasing r and provides the firmest piece of evidence in support of the hypothesis that large amounts of dark matter may be present in the halos of spiral galaxies.

The qualitative fact of disk galaxies rotating differentially, with the inner parts having shorter rotational periods than the outer parts, has been known since Lindblad's and Oort's investigations of the problem for the Milky Way system in the 1920s. This fact, combined with age estimates for all galaxies of about 10^{10} years, presents a dilemma for the origin of spiral structure. If spiral arms are viewed as consisting always of the same material (*e.g.*, the same gas clouds that give birth to the brilliant OB stars and H II regions that best define the optical spiral structure), then the arms should wind up. In particular, with a flat rotation curve, material at half the solar distance from the galactic centre should go around twice for each revolution of the material at the solar distance, and an extra turn should then be added to each spiral arm between these two radii every 2.5×10^8 years. This would give the spiral arms of the Galaxy (and other spiral galaxies like it) several dozens of turns over the lifetime of the Galaxy, whereas spiral galaxies have in fact never been observed with more than one or two turns.

A way out of the winding dilemma is the proposal that spiral structure is a wave phenomenon, the spiral arms being a local "piling-up" of stars and gas clouds that individually flow through the spiral pattern, much as a traffic jam is a local piling-up of cars and trucks that individually flow through the jam. The piling-up arises because the self-gravity of the excess matter in the arms causes deflections of what would otherwise be circular orbits (on average), the deflections self-consistently producing the original pileup.

The concept of density waves

Most astronomers are agreed that density waves underlie the phenomenon of spiral structure in the so-called grand-design galaxies. More controversial is whether some other mechanism (*e.g.*, "stochastic star formation") might play a role in galaxies where the spiral structure is "flocculent."

In modern density-wave theory, as developed by the American mathematician Chia-chiao Lin and his associates, spiral structure represents an unstable mode of collective oscillation. The instability provides a way by which a differentially rotating disk galaxy may release free energy of differential rotation and spontaneously generate spiral waves. The balance of the growth of these waves against their dissipation (through the response of the interstellar gas clouds) may yield a quasi-stationary state whereby gaseous matter slowly drifts to the interior and angular momentum is steadily transported to the exterior. Although the details of the entire picture remain incomplete, many of the basic predictions—as, for example, that the perturbations in density and velocity should be strongest in the component with the smallest random velocities (*i.e.*, gas and dust clouds)—have already been confirmed both qualitatively and quantitatively in several well-observed spiral galaxies. Furthermore, the Hubble correlation between the tightness of spiral windings and the size of the central bulge relative to the disk, as well as the van den Bergh correlation between luminosity class and the degree of organization of the spiral structure, are simple direct consequences of density-wave theory.

A similar explanation probably underlies the barred spiral galaxies, with the basic underlying disturbance being an oval distortion. The predicted departures from circular motions are larger in barred spirals than in ordinary spirals, and this seems to be consistent with the observational evidence that currently exists for this problem. The enhanced rates at which matter is brought to the centres of such galaxies may have implications for various energetic events that take place in some galactic nuclei. It has even been proposed on the basis of observed peculiarities of gas motions and various infrared images that the central regions of the Milky Way Galaxy may contain a small bar.

In elliptical galaxies, the constituent stars have random velocities that are generally much larger than the rotational motions. This explains why ellipticals possess neither thin disks nor spiral arms. Moreover, giant ellipticals are flatter than would be inferred from the amount of rotation that they do possess, and increasing rotation does not necessar-

ily lead to increasing flattening, as appears to happen, for example, to ellipticals of lower luminosity and the bulges of spiral galaxies. Also, most ellipticals do not appear to have young stars, probably because the small measurable amounts of gas and dust that exist in them cannot support an active rate of star formation.

Mathematical analysis and computer simulations since the early 1970s suggest a possible stellar-dynamic basis for understanding the basic shapes of giant elliptical galaxies. Unlike the bulges and disks of S0 galaxies, the bodies of giant ellipticals may not be figures of revolution (*e.g.*, oblate spheroids) but may possess three axes of unequal lengths. In the models, the triaxial shape arises because the random velocities of the stars are anisotropic (not equal in all directions). Such a state of affairs seems consistent with the existing observational data, in particular the finding in several ellipticals that significant rotation exists around the longest apparent axis. A healthy fraction of nearby ellipticals, moreover, show rapidly rotating cores, which may represent the remains of captured dwarf galaxies that have spiraled to the centres of their larger hosts.

An interesting empirical property shared by both ellipticals and spirals is that their luminosities L seem to be proportional to the fourth power of their random or circular velocities V. The proportionality constant can be calibrated with the help of nearby (giant) galaxies, and the resulting relation may then be used for cosmological investigations. In particular, the determination of distances is a recurring astronomical problem, and the relation, L proportional to V^4, provides a method for obtaining distances. In brief, a measurement of V allows the determination of L, which, combined with the observed apparent brightness, gives the distance of the object.

Interacting galaxies. Strongly interacting pairs of galaxies make up less than 1 percent of all galaxies, but the more spectacular examples produce intriguing structures (bridges, tails, rings, and shells) and involve processes (stripping, merging, and sinking) that are not present in individual isolated galaxies. Computer simulations of the gravitational encounter between a large disk galaxy and a small one show that the latter can pull material from the near side of the former into a bridge that temporarily spans the gulf between the two. Encounters between two more nearly equal participants can yield one long tail from each disk galaxy, which extends away from the main bodies (Figure 1). Rings emerge in the disk of a galaxy if another massive galaxy passes through its body; the brief inward pull and subsequent rebound cause the orbits of the rings to pile together like ripples on the surface of a pond into which a stone is dropped. Shells form across the face of a large elliptical galaxy if it devours a small companion; the stars of the small galaxy are strewn like wine out of a rolling barrel with the stopper removed.

Gravitational encounters between galaxies

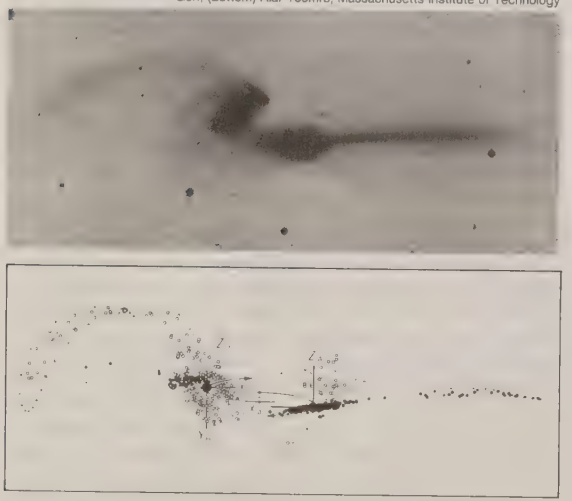

Figure 1: *The interacting galaxies NGC 4676A and B.* (Top) A negative print of these two nearly equal-sized disk galaxies shows that the close encounter between the pair has resulted in the formation of a long "tail" from each. (Bottom) A computer simulation of the same strongly interacting galaxies reveals their structures more clearly.

Stripping (of matter), merging (of the main bodies of the galaxies), and sinking (of the satellite galaxy toward the centre of the host) are all represented in the above example, and these processes, individually and collectively, have been invoked by theorists in a wide variety of contexts and by a wide variety of names to explain different observed galactic phenomena. The most interesting application is perhaps to the origin of elliptical galaxies.

It has been proposed by the American astronomer-mathematician Alar Toomre that elliptical galaxies result from the merger of spiral galaxies, jumbled piles of stars from the wreckage of collisions of bound pairs of galaxies with arbitrarily oriented spins and orbits. A potential difficulty with the original theory was the fate of the interstellar gas and dust. Considerable evidence has since accumulated (*i.e.*, with the launch in 1983 of the Infrared Astronomical Satellite [IRAS]) to show that tidal interactions and galactic mergers can induce strong bursts of star formation that use up the interstellar material at rates up to 100 times faster than in normal galaxies (see below). An extension of similar ideas suggests that the supergiant ellipticals, the cD galaxies that tend to lie at or near the centres (or density maxima) of rich clusters of galaxies, grew bloated by "cannibalizing" their smaller neighbours.

Galaxy formation. Some years ago, astronomers thought that galaxies formed at a time when the universe was a few times 10^8 years of age, since this is also the time matter takes to cross a typical galaxy by coherent dynamic collapse of a large gas cloud at free-fall speeds. In the process of so contracting, neighbouring protogalaxies would exert gravitational torques on each other, imparting amounts of angular momenta comparable to that possessed by galaxies today. The bodies would therefore flatten in the subsequent collapse.

Material that reached a completely flattened state while still in a gaseous state would have its vertical component of motion arrested in a strong shock wave and form the disk of a galaxy. Material that formed dense stars or protostars on the way down would be able to pass through the disk virtually unimpeded and, after several bounces, would settle to form the bulge and halo of a disk galaxy like the Milky Way system. It was also thought that a slight modification could produce elliptical galaxies—namely, if the efficiency of star formation were so high during the collapse phase that virtually all the matter turned into stars before flattening into a disk, then a single quasi-spherical stellar component might result. Given the developments since the 1970s described above, however, serious doubts have been raised against this scenario. The spread in ages and heavy-element abundances of halo and bulge stars in the Milky Way Galaxy, the anisotropic distribution of stellar velocities in elliptical galaxies, and the statistics of starburst galaxies and interacting galaxies all argue for the importance of galactic mergers (perhaps involving predominantly dwarf systems) in the buildup of giant galaxies.

There also exists observational evidence that galaxies existent at a time corresponding to a redshift of three or four have properties quite different from those that exist today at redshifts near zero (see *Cosmological models* below). High-redshift galaxies can be found in association with strong extragalactic radio sources (see below *Quasars and related objects*), and, when such galaxies are imaged optically, they often show complex lumpy structures suggestive of recent mergers and interactions. A similar result applies when distant galaxies were imaged in a random fashion by the Hubble Space Telescope, the Earth-orbiting observational system launched in 1990.

It remains uncertain, however, when the first stars in any galactic-sized lump formed. Infrared studies demonstrate that well-developed stellar populations already exist in galaxies with redshifts of a few and perhaps even 5 or 10. The observational discovery of a genuine primeval galaxy would remove many uncertainties. In a collapse environment involving only hydrogen and helium gas, the primary diagnostic would be the copious emission of Lyman-alpha radiation (corresponding to the transition between the first

Search for a primeval galaxy

excited state and the ground state of atomic hydrogen). The rest wavelength of this transition lies in the ultraviolet, but in primeval galaxies the cosmological redshift would make the observed wavelength longer (*i.e.,* toward the red end of the spectrum). From this point of view, it is interesting that searches near known quasars have uncovered Lyman-alpha-emitting galaxies with redshifts exceeding three.

There exists a body of opinion that the stars of a primeval galaxy will generate dust at such a rapid rate that all intrinsic Lyman-alpha production by the galaxy will be degraded to thermal infrared-continuum radiation. In this case, primeval galaxies may resemble the "starburst galaxies" that were discovered by IRAS. In contrast to normal galaxies like the Milky Way system where the ratio of infrared to visible luminosities is about unity, these sources can emit up to 100 times more infrared radiation than visible light. The only viable explanation for the infrared excess is that these galaxies are somehow undergoing enormous bursts of star formation. Ground-based observations that followed up the IRAS discovery showed that the activity in starburst galaxies is often confined to the central portions of the systems and that many of the candidate sources correspond either to interacting galaxies or to barred spirals. This suggests that starbursts may be triggered by the gravitational perturbations that have brought large amounts of molecular gas to the central regions of the galaxy. A similar burst of star formation might be expected to occur in an era when the matter of a galaxy was nearly all gas rather than all stars. Since astronomers have not found any general evidence for such large-scale energetic events, it becomes plausible to contemplate the formation of giant galaxies as a more protracted process (through the mergers of many dwarf systems), extending possibly even to the present epoch.

QUASARS AND RELATED OBJECTS

Galaxies are where astronomers find stars, the major transformers of matter into energy in the universe. Paradoxically, it is also from the study of galaxies that astronomers first learned that there exist in the universe sources of energy individually much more powerful than stars. These sources are radio galaxies and quasars, and their discovery in the 1950s and '60s led to the establishment of a new branch of astronomy, high-energy astrophysics.

Extragalactic radio sources. Sources that emit a continuum of radio wavelengths and that lie beyond the confines of the Galaxy were divided in the 1950s into two classes depending on whether they present spatially extended or essentially "starlike" images. Radio galaxies belong to the former class, and quasars (short for "quasi-stellar radio sources") to the latter. The distinction is somewhat arbitrary, because the ability to distinguish spatial features in cosmic radio sources has improved steadily and dramatically over the years, owing to Sir Martin Ryle's introduction of arrays of telescopes, which use aperture-synthesis techniques to enhance the angular resolution of a single telescope. Apart from the smaller angular extent that arises from being at a greater distance, many objects originally classified as quasars are now known to have radio structures that make them indistinguishable from radio galaxies. Not every quasar, however, is a radio galaxy. For every radio-loud quasar, there exist 20 objects having the same optical appearance but not the radio emission. These radio-quiet objects are called QSOs for quasi-stellar objects. Henceforth, the term quasars will be used to refer to both quasars and QSOs when the matter of radio emission is not under discussion.

Double-lobed radio sources

The most powerful extragalactic sources of radio waves are double-lobed sources (or "dumbbells") in which two large regions of radio emission are situated in a line on diametrically opposite sides of an optical galaxy. The parent galaxy is usually a giant elliptical, sometimes with evidence of recent interaction. The classic example is Cygnus A, the strongest radio source in the direction of the constellation Cygnus. Cygnus A was once thought to be two galaxies of comparable size in collision, but more recent ideas suggest that it is a giant elliptical whose body is bifurcated by a dust lane from a spiral galaxy that it recently swallowed. The collisional hypothesis in its original form was abandoned because of the enormous energies found to be needed to explain the radio emission.

The radio waves coming from double-lobed sources are undoubtedly synchrotron radiation, produced when relativistic electrons (those traveling at nearly the speed of light) emit a quasi-continuous spectrum as they gyrate wildly in magnetic fields. The typical spectrum of the observed radio waves decreases as a power of increasing frequency, which is conventionally interpreted, by analogy with the situation known to hold for the Galaxy in terms of radiation by cosmic-ray electrons, with a decreasing power-law distribution of energies. The radio waves typically also show high degrees of linear polarization, another characteristic of synchrotron radiation in well-ordered magnetic fields.

A given amount of received synchrotron radiation can be explained in principle by a variety of assumed conditions. For example, a high energy content in particles (relativistic electrons) combined with a low content in magnetic fields will give the same radio luminosity as a low energy content in particles combined with a high content in magnetic fields. The American astrophysicist Geoffrey R. Burbidge showed that a minimum value for the sum results if one assumes that the energy contents of particles and fields are comparable. The minimum total energy computed in this way for Cygnus A (whose distance could be estimated from the optical properties of the parent galaxy) proved to be between 10^{60} and 10^{61} ergs.

Underlying source of power

A clue to the nature of the underlying source of power came from aperture-synthesis studies of the fine structure of double-lobed radio galaxies. It was found that many such sources possess radio jets that point from the nuclei of the parent galaxies to the radio lobes. It is now believed, largely because of the work of Sir Martin Rees and Roger Blandford, that the nucleus of an active galaxy supplies the basic energy that powers the radio emission, the energy being transported to the two lobes by twin beams of relativistic particles. Support for this theoretical picture exists, for example, in VLA maps (those made by the Very Large Array of radio telescopes near Socorro, N.M., U.S.) of Cygnus A that show two jets emerging from the nucleus of the central galaxy and impacting the lobes at "hot spots" of enhanced emission (Figure 2). Other examples of this type are known, as are "head-tail" sources such as NGC 1265 where the motion of an active galaxy through the hot gas that exists in a cluster of galaxies has apparently swept back the jets and lobes in a characteristic U shape.

Many jets are one-sided; *i.e.,* only one of the postulated twin jets is actually observed. This is usually interpreted to mean that the material in some jets moves relativistically (at speeds approaching that of light). Relativistic effects—*e.g.,* the Doppler shift of the emitted photons—then boost the intrinsic luminosity of the jet pointing toward the observer and lower that of the counterjet, allowing measurements of limited dynamic range to detect only the former.

Support for the interpretation of relativistic jets exists in the phenomenon of "superluminal expansion." In very long baseline interferometry (VLBI) experiments performed by combining the simultaneous observations of several telescopes spaced by thousands of kilometres, radio astronomers have discovered that some of the compact radio sources located in the nuclei of active galaxies break into several components at high angular resolution. Moreover, in the course of a few years, the components move with respect to each other along a line projected against the sky that points toward more extended structures known from other observations (*e.g.,* large jets or lobes). If the source is placed at a (cosmological) distance appropriate for the redshift of the optical object, the projected motion across the line of sight has an apparent velocity that exceeds the speed of light. For example, in 3C 273, which possesses an optical jet in addition to the radio features discussed here, the apparent velocity measured over a time span from mid-1977 to mid-1980 amounted to about 10 times the speed of light.

Clearly, if Einstein's theory of special relativity is correct and if the assumed distance of the object is justified, then the computed "velocity" cannot represent the actual ve-

Figure 2: A series of three radiographs produced by the Very Large Array (VLA) of the double-lobed radio galaxy Cygnus A at six-centimetre wavelength. The radio jet extending from the core to the northwest lobe (right) is readily seen, but evidence for a counterjet to the southeast lobe (left) is marginal.

The National Radio Astronomy Observatory, operated by Associated Universities, Inc., under contract with the National Science Foundation; observers, Richard A. Perley, John W. Dreher, and John J. Cowan

locity of ejected collections of particles. The explanation now accepted by most astronomers is the model of a relativistic beam directed at a small angle to the observer along the line of sight. In this model a particle moving close to the speed of light would, according to a distant observer, almost catch up with the photons it emits, so that the duration of time that elapses between an earlier emission event and a later one is systematically underestimated by the observer (compared with one moving with the beam). Thus, under the appropriate circumstances, the apparent velocity (distance across the line of sight divided by apparent elapsed time) can exceed the actual velocity by a large factor. A beam moving at an actual velocity 99.5 percent the speed of light along an angle that lies 6° from the line of sight, for example, will seem to move across the line of sight at an apparent velocity of 10 times the speed of light.

Quasars. The source 3C 273 mentioned above is officially classified by astronomers as a quasar. Quasars were first detected as unresolved sources in surveys conducted during the 1950s by radio astronomers in Cambridge, Eng. Optical photographs subsequently taken of their spectra showed locations for emission lines at wavelengths that were at odds with all celestial sources then familiar to astronomers. The puzzle was solved by the American astronomer Maarten Schmidt, who announced in 1963 that the pattern of emission lines in 3C 273 could be understood as coming from hydrogen atoms that had a redshift of 0.158. In other words, the wavelength of each line was 1.158 times longer than the wavelength measured in the laboratory where the source is at rest with respect to the observer. (The general formula is that, if the factor is $1 + z$, astronomers say the astronomical source has a redshift of z. If z turns out to be negative [*i.e.*, if $1 + z$ is less than 1], the source is said to be "blueshifted.")

Enormous redshifts of quasars

Schmidt's discovery raised immediate excitement, since 3C 273 had a redshift whose magnitude had been seen theretofore only among the most distant galaxies. Yet it had a starlike appearance, with an apparent brightness (but not a spectrum) in visible light not very different from that of a galactic star at a distance of a few thousand light-years. If the quasar lay at a distance appropriate to distant galaxies a few times 10^9 light-years away, then the quasar must be 10^{12} times brighter than an ordinary star. Similar conclusions were reached for other examples. Quasars seemed to be intrinsically brighter than even the most luminous galaxies known, yet they presented the pointlike image of a star.

A hint of the actual physical dimensions of quasars came when sizable variations of total light output were seen from some quasars over a year or two. These variations implied that the dimensions of the regions emitting optical light in quasars must not exceed a light-year or two, since coherent fluctuations cannot be established in any physical object in less time than it takes photons, which move at the fastest possible speed, to travel across the object. These conclusions were reinforced by later satellite measurements that showed that many quasars had even more X-ray emission than optical emission, and the total X-ray intensity could vary in a period of hours. In other words, quasars released energy at a rate exceeding 10^{12} suns, yet the central machine occupied a region only the size of the solar system.

Understandably, the implications were too fantastic for many people to accept, and a number of alternative interpretations were attempted. An idea common to several of the alternatives involved the proposal that the redshift of quasars arose from a different (*i.e.*, noncosmological) origin than that accepted for galaxies. In that case, the distance to the quasars could be much less than assumed to estimate the energy outputs, and the requirements might be drastically relaxed. None of the alternative proposals, however, withstood close examination.

Evidence for the cosmological distances of quasars

In any case, there now exists ample evidence for the validity of attributing cosmological distances to quasars. The strongest arguments are the following. When the strong nonstellar light from the central quasar is eliminated by mechanical or electronic means, a fuzzy haze can sometimes be detected still surrounding the quasar. When this light is examined carefully, it turns out to have the colour and spectral characteristics appropriate to a normal giant galaxy. This suggests that the quasar phenomenon is related to nuclear activity in an otherwise normal galaxy. In support of this view is the observation that quasars do not really form a unique class of objects. For example, not only are there elliptical galaxies that have radio-emission characteristics similar to those of quasars, but there are weaker radio sources among spiral galaxies (called Seyferts after their discoverer, the American astronomer Carl K. Seyfert), which have bright nuclei that exhibit qualitatively the same kinds of optical emission lines and nonstellar continuum light seen in quasars. There also are elliptical galaxies, N galaxies, and the so-called BL Lac objects, which have nuclei that are exceptionally bright in optical light. Plausible "unification schemes" have been proposed to explain many of these objects as the same intrinsic structure but viewed at different orientations with respect to relativistically beamed jets or with obscuring dust tori surrounding the nuclear regions or both. Finally, a number of quasars—including the closest example, the famous source 3C 273—have been found to lie among clusters of galaxies. When the redshifts of the cluster galaxies are measured, they have redshifts that bracket the quasar's, suggesting that the quasar is located in a galaxy that is itself a cluster member.

Black-hole model for active galactic nuclei. The fact that the total output from the nucleus of an active galaxy

Mechanisms for energy release

can vary by substantial factors supports the argument that the central machine is a single coherent body. A competing theory, however, holds that the less powerful sources may be understood in terms of multiple supernova explosions in a confined space near the centres of starburst galaxies. Nevertheless, for the most powerful cases, the theoretical candidate of choice is a supermassive black hole that releases energy by the accretion of matter through a viscous disk. The idea is that the rubbing of gas in the shearing layers of a differentially rotating disk would frictionally generate heat, liberating photons as the mass moves inward and the angular momentum is transported outward. Scaled-down versions of the process have been invoked to model the primitive solar nebula and the disks that develop in interacting binary stars.

The black hole has to be supermassive for its gravitational attraction to overwhelm the strong radiation forces that attempt to push the accreting matter back out. For a luminosity of 10^{46} erg/sec, which is a typical inferred X-ray value for quasars, the black hole must exceed 10^8 solar masses. The event horizon of a 10^8 solar-mass black hole, from inside which even photons would not be able to escape, has a circumference of about two light-hours. Matter orbiting in a circle somewhat outside of the event horizon would be hot enough to emit X rays and have an orbital period of several hours; if this material is lumpy or has a nonaxisymmetric distribution as it disappears into the event horizon, variations of the X-ray output on a time scale of a few hours might naturally be expected.

To produce 10^{46} erg/sec, the black hole has to swallow about two solar masses per year if the process is assumed to have an efficiency of about 10 percent for producing energy from accreted mass. The rough estimate that 10 percent of the rest energy of the matter in an accretion disk would be eventually liberated as photons, in accordance with Einstein's formula $E = mc^2$, should be contrasted with a total efficiency of about 1 percent in nuclear reactions if a mass of hydrogen were to be converted entirely into iron. If the large-scale annihilation of matter and antimatter is excluded from consideration, the release of gravitational binding energy when matter settles onto compact objects is the most powerful mechanism for generating energy in the known universe. (Even supernovas use this mechanism, for most of the energy released in the explosion comes from the gravitational binding energy or mass deficit of the remnant neutron star.)

Interacting and merging galaxies provide the currently preferred routes to supply the matter swirling into the black hole. The direct ingestion of a gas-rich galaxy yields an obvious external source of matter, but the enhanced accretion of the parent galaxy's internal gas through tidal interactions (or bar formation) may suffice in most cases. At lower luminosities, other contributing factors may come from the tidal breakup of stars passing too close to the central black hole or from the mass loss from stars in the central regions of the galaxy. Gathering matter at a rate of two solar masses per year (90 percent of which ends up as the gravitating mass of the black hole) will build up a black hole of 10^8 solar masses in several tens of millions of years. This estimate for the lifetime of an active galactic nucleus is in approximate accord with the statistics of such objects. This does not imply that supermassive black holes at the centres of galaxies necessarily accumulate from a seed of very small mass by steady accretion. There remain many viable routes for their formation, the study of such processes being in a state of infancy.

Observational tests. If there are supermassive objects at the centres of elliptical galaxies, gravitational perturbations of the spatial distribution or velocity field of nearby stars may be discernible. For a spherical distribution of stars surrounding a black hole, theoretical calculations indicate that the number of stars per unit volume and the dispersion of random velocities should rise, respectively, as the negative 7/4 power and the negative 1/2 power of the radial distance from the black hole. In other words, rather than gently rounded or flat profiles as the centre is approached, cusps of stellar light and random velocities should be seen, the upturn beginning at a radial distance where the escape velocity from the black hole is comparable to the natural dispersion of random velocities in the central regions of an elliptical galaxy.

Except for the largest black holes or the nearest galaxies, the region interior to the turnup point is not resolvable by ground-based optical telescopes, because of the blurring effects produced by turbulence in the Earth's atmosphere. Excess central starlight and velocity dispersions have been seen in M87—a giant elliptical with a well-known optical jet emerging from its nucleus, which is located in the Virgo cluster, the nearest large cluster of galaxies. The excesses are consistent with a central black hole of several times 10^9 solar masses. Atmospheric blurring, however, prevents astronomers from determining whether the upturns represent true cusps or merely shoulders that taper to constant values. Mere shoulders could be explained, without invoking a black hole, by the stars in the central regions of this galaxy having a nonstandard distribution of random velocities.

A better situation exists for the detection of supermassive black holes in the nuclei of spiral galaxies, since the interpretation of organized rotational motions is simpler than that for disorganized random motions. The Andromeda galaxy has an excess component of light within a few light-years of its centre. High-resolution spectroscopy of this region shows a large velocity width indicative of the presence of a black hole in the nucleus with a mass in excess of 10^7 solar masses. Similar observations carried out for more distant spiral galaxies have yielded good candidates for supermassive black holes with masses ranging up to 10^9 solar masses.

The closest galactic nucleus of all is of course located at the centre of the Milky Way Galaxy. Unfortunately, the nucleus of the system is not observable at the wavelengths of visible light, ultraviolet light, or soft X rays (those of lower energy than hard X rays), because of the heavy absorption by intervening dust. It can be probed by radio, infrared, hard X-ray, and gamma-ray techniques; such studies have revealed many intriguing features.

Sagittarius A*

The most likely candidate for the nucleus of the Galaxy has long been regarded to be a compact radio-continuum source denoted Sagittarius A*. This synchrotron-radiation source is unique in the Galaxy: it is variable on a time scale of one day, implying that the radio emission arises from a region with dimensions smaller than the solar system; it shows evidence for synchrotron self-absorption, a condition consistent with a region being compactly filled with relativistic particles and fields; and measurements obtained with VLBI indicate that its motion with respect to the centre of the Galaxy is less than 40 km/sec, consistent with a heavy object brought to rest by "dynamic friction" in the deepest part of the Galaxy's potential well. Hard X-ray observations of the galactic central region, however, reveal only low-level emission from a diffuse component and several discrete sources with characteristics similar to coronal emission from luminous young stars. Broadband, near-infrared measurements at a wavelength centred near 2 micrometres (0.002 millimetre) show the presence of a dense star cluster. Surprisingly, the maximum concentration of light of the star cluster does not seem to centre on Sagittarius A*, nor does it show the $r^{-7/4}$ light cusp expected for the distribution of stars surrounding a massive pointlike object. Perhaps the cluster appears only by chance projection against the radio source.

Spectroscopic investigations of the molecular and ionized gas yield a more promising interpretation. Molecular gas in a tilted ring within several light-years of the galactic centre exhibits rotational velocities consistent with motion under a central force field of an object having a mass of several million solar masses. Unfortunately, the molecular gas disappears before the centre can be approached very closely; fortunately, its disappearance is compensated by the appearance of ionized gas forming a "mini-spiral" within the central few light-years. One of the three arms of the mini-spiral streams within one light-year of Sagittarius A*. If this streamer is modeled as an infalling parabolic trajectory, a value of 4×10^6 solar masses is obtained for a compact object at the nucleus of the Galaxy. If the Galaxy has a central black hole, this is probably the best estimate of its mass.

Radio-continuum studies on a scale of hundreds of light-years from the Galaxy's centre show the nucleus to be embedded in an extraordinary set of filamentary arcs that pass perpendicularly through the galactic plane. Magnetic fields 1,000 times stronger than the general galactic field may play a role in defining the filaments, perhaps in a fashion analogous to the eruption of solar prominences. These magnetic fields may also have restrained the unusual massive molecular clouds Sagittarius A and Sagittarius B2 from forming OB stars with the same vigour as their counterparts farther out in the disk. Details such as these can be seen only because the nucleus of the Galaxy is so close (a "mere" 30,000 light-years away). This complexity should serve as a sobering reminder that most theoretical models of the active nuclei of external galaxies must vastly oversimplify the actual state of affairs.

OTHER COMPONENTS

Every second of every day, the Earth is bombarded by high-speed particles, electromagnetic radiation, and perhaps gravitational waves of cosmic origin. As has already been discussed, a part of this steady rain is, directly or indirectly, of planetary, stellar, or galactic origin, but another part may be a relict from a time in the universe before there were any planets, stars, or galaxies.

Cosmic rays and magnetic fields. In the years following the discovery of natural radioactivity by the French physicist Henri Becquerel in 1896, investigators used ionization chambers to detect the presence of the fast charged particles that are produced in the phenomenon. These workers found that low-level ionization events still occurred even when the source of radioactivity was removed. The events persisted with heavy shielding, and in 1912 the American physicist Victor F. Hess found that they increased drastically in intensity if the detecting instruments were carried to high altitudes by balloons. Little difference existed between day and night; thus, the Sun could not be the primary source. The penetrating radiation had to have a cosmic component, and the earliest suggestion was that it was composed of high-energy photons, gamma rays—hence, the name cosmic rays. In 1927 it was shown that the cosmic-ray intensity was higher at the magnetic poles than at the magnetic equator. For the incoming trajectories to be affected by the geometry of the Earth's magnetic field, cosmic rays had to be charged particles.

Cosmic-ray composition

It is now known that cosmic rays come with both signs of electric charge and with a wide distribution of energies. About 83 percent of the positively charged component of cosmic rays consists of protons, the nuclei of hydrogen atoms, and about 16 percent of alpha particles, the nuclei of helium atoms (Figure 3). The nuclei of heavier atoms occur roughly in their cosmic abundances except that the light elements lithium, beryllium, and boron—which are quite rare elsewhere in the universe—are vastly overrepresented in the cosmic rays. The negatively charged component consists of mostly electrons at a level of 1 percent of the protons. Positrons also can be found, approximately 10 percent as frequently as electrons. A very small contribution from antiprotons is also known. Cosmic-ray positrons and antiprotons are believed to be by-products of collisions between the nuclei of cosmic rays with the ambient atomic nuclei that exist in interstellar gas clouds. Cosmic gamma rays, which have been detected emanating from the Milky Way and show a strong correlation with the distribution of interstellar gas, are another manifestation of such collisions.

The cosmic-ray protons that freely enter the solar system, despite the outward sweep of the solar wind and the magnetic fields it carries, have energies that vary from a few times their rest energies to 10^6 times and more. Thus, these particles must move at speeds approaching the speed of light. In this range the number of particles at energy E varies with E to the negative 2.7 power. A similar decreasing power law seems to hold for cosmic-ray electrons with energies from a few thousand to tens of thousands times their rest energies. Within uncertainties this energy distribution is consistent with the synchrotron-radiation interpretation of the nonthermal radio emission from the Galaxy. At higher energies, there are fewer cosmic-ray electrons than predicted by extrapolation of the power law found at lower energies, and this depletion can be understood on the basis of the large synchrotron-radiation losses suffered by the most energetic electrons.

Above 10^7 times the rest energy of the proton, there also are fewer positively charged particles than predicted by the extrapolation of the power law $E^{-2.7}$; however, synchrotron losses cannot account for this deficiency. A more likely interpretation is that the cosmic-ray nuclei of lower energies are commonly produced and confined to the Galaxy, whereas those with very high energies may have an origin in very exotic or even extragalactic objects. This is consistent with the fact that protons with energies less than 10^7 times their rest energies would be bent by the interstellar magnetic field to follow spiraling trajectories that would be confined to the thickness of the galactic disk. Nevertheless, these particles can eventually escape from the disk if the magnetic fields buckle out of the galactic plane (as they do because of certain instabilities).

An estimate of the total residence time of cosmic-ray nuclei within the disk of the Galaxy can be obtained by examining the anomalous abundances of lithium, beryllium, and boron. These elements are only somewhat less abundant in cosmic rays than carbon, nitrogen, and oxygen, and this has been conventionally interpreted to mean that the former group was mostly produced by spallation reactions (breakup of heavier nuclei) of the latter group as the cosmic-ray particles traversed interstellar space and interacted with the matter there. From the amount of spallation that has occurred, it can be estimated that the cosmic rays reside, on average, roughly 10^7 years among the gas clouds in the galactic disk before escaping.

Origin of cosmic rays

The origin of cosmic rays is an incompletely resolved problem. At one time astronomers believed that all cosmic rays, except those at the highest energies, originated with supernova explosions. The total energetics is right, and the presence in cosmic rays of nuclei as heavy as iron, etc., could receive a natural explanation under the supernova hypothesis. Unfortunately, doubt was cast on the hypothesis by later work that questioned, first, whether particles could really be accelerated to cosmic-ray energies in a single supernova shock and, second, whether these particles, even if accelerated, could propagate through the interstellar medium very far from the site of the original

By courtesy of P. Buford Price

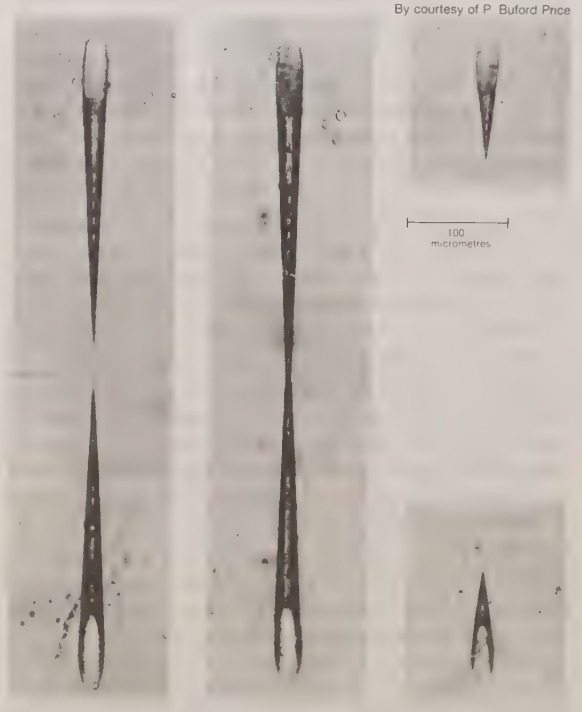

Figure 3: Cosmic-ray particles traversing a sheet of Lexan plastic leave ionization tracks on it. These tracks are made visible by chemical etching. The properties of the tracks and the subsequent etch patterns depend on the energy loss of the particles.

explosion. The second objection also applies to other possible point sources, such as pulsars.

Shock-acceleration model

A more promising possibility seems to be the proposal that cosmic rays are accelerated to their high energies by repeated reflections in magnetic shock waves in the interstellar medium (whose ultimate energy may be derived from the ensemble of all supernova explosions). The idea is that gas and the magnetic field threading it move at very different speeds on the two sides of the front of a shock wave. Cosmic-ray particles rattling through magnetic inhomogeneities may be shuttled back and forth between these two regions, gaining statistically an extra boost in energy every time they "bounce" off the moving set of magnetic field lines. The process is akin to the increasing energy that would be gained by a tennis ball in the absence of air drag if it were banged back and forth between a vigorously swinging player and a stationary wall. The great attractiveness of the strong shock-wave picture for accelerating cosmic rays is that it automatically gives, in the simplest models, a decreasing power-law distribution of particle energies. The exponent is 2 instead of the measured 2.7, and the discrepancy is believed to be related to an energy-dependent escape rate from the region of acceleration. The enhancement of the escape rate with increasing energy is not completely understood, but no fundamental obstacle appears likely in this direction to rule out the shock-acceleration model.

More serious failings of the shock-acceleration model are that it does not address the acceleration of cosmic-ray electrons, nor does it easily explain the origin of ultra-high-energy cosmic rays, nuclei with energies that lie between 10^8 and 10^{11} times the rest energy of the proton. There is some indication from measurements of ultra-high-energy gamma rays from some binary X-ray sources that these objects may copiously produce ultra-high-energy cosmic rays, but the exact acceleration mechanism remains obscure. At the highest observed cosmic-ray energies, the particles arrive preferentially from northern galactic latitudes, a fact interpreted by some to indicate a large contribution from the Virgo supercluster. In this picture even higher-energy cosmic rays from more distant parts of the universe (greater than about 10^8 light-years) do not reach the Earth, because such particles would suffer serious losses en route as they interact with the photons of the cosmic microwave background.

Microwave background radiation. Beginning in 1948, the American cosmologist George Gamow and his coworkers, Ralph Alpher and Robert Herman, investigated the idea that the chemical elements might have been synthesized by thermonuclear reactions that took place in a primeval fireball. The high temperature associated with the early universe would give rise to a thermal radiation field, which has a unique distribution of intensity with wavelength (known as Planck's radiation law), that is a function only of the temperature. As the universe expanded, the temperature would have dropped, each photon being redshifted by the cosmological expansion to longer wavelength, as the American physicist Richard C. Tolman had already shown in 1934. By the present epoch the radiation temperature would have dropped to very low values, about 5° above absolute zero (0 K, or −273° C) according to the estimates of Alpher and Herman.

Interest in these calculations waned among most astronomers when it became apparent that the lion's share of the synthesis of elements heavier than helium must have occurred inside stars rather than in a hot big bang. In the early 1960s physicists at Princeton University, N.J., as well as in the Soviet Union, took up the problem again and began to build a microwave receiver that might detect, in the words of the Belgian cleric and cosmologist Georges Lemaître, "the vanished brilliance of the origin of the worlds."

Discovery of relict radiation

The actual discovery of the relict radiation from the primeval fireball, however, occurred by accident. In experiments conducted in connection with the first Telstar communication satellite, two scientists, Arno Penzias and Robert Wilson, of the Bell Telephone Laboratories, Holmdel, N.J., measured excess radio noise that seemed to come from the sky in a completely isotropic fashion. When they consulted Bernard Burke of the Massachusetts Institute of Technology, Boston, about the problem, Burke realized that Penzias and Wilson had most likely found the cosmic background radiation that Robert H. Dicke, P.J.E. Peebles, and their colleagues at Princeton were planning to search for. Put in touch with one another, the two groups published simultaneously in 1965 papers detailing the prediction and discovery of a universal thermal radiation field with a temperature of about 3 K.

Precise measurements made by the Cosmic Background Explorer (COBE) satellite launched in late 1989 determined the spectrum to be exactly characteristic of a blackbody at 2.735 K. The velocity of the satellite about the Earth, the Earth about the Sun, the Sun about the Galaxy, and the Galaxy through the universe actually makes the temperature seem slightly hotter (by about one part in 1,000) in the direction of motion rather than away from it. The magnitude of this effect—the so-called dipole anisotropy—allows astronomers to determine that the Local Group of galaxies is moving at a speed of about 600 km/sec in a direction that is 45° from the direction of the Virgo cluster of galaxies. Such motion is not measured relative to the galaxies themselves (the Virgo galaxies have an average velocity of recession of about 1,000 km/sec with respect to the Milky Way system) but relative to a local frame of reference in which the cosmic microwave background radiation would appear as a perfect Planck spectrum with a single radiation temperature.

"Dipole anisotropy"

The origin of the "peculiar velocity" of 600 km/sec for the Local Group presents an interesting problem. A component of this velocity may be induced by the gravitational attraction of the excess mass above the cosmological mean represented by the Virgo cluster; however, it is now believed that the Virgo component is relatively small, at best 200–300 km/sec. A more important contribution may come from the mass of a "Great Attractor" at a distance of 10^8 light-years connected to the Local Supercluster, but this interpretation is somewhat controversial since much of the supposed grouping lies behind the obscuration of the plane of the Milky Way. In any case, the generation of the large peculiar velocity of the Local Group of galaxies probably requires invoking an augmentation in dark matter of the gravitational attraction of the observable galaxies by a factor of roughly 10.

The COBE satellite carried instrumentation aboard that allowed it to measure small fluctuations in intensity of the background radiation, not just in the sense of a forward-backward asymmetry but also on angular directions in the sky that correspond to distance scales on the order of 10^9 light-years across (still larger than the largest material structures seen in the universe, such as the enormous grouping of galaxies dubbed the "Great Wall"). Figure 4A shows what the intensity pattern looks like in angular projection at a wavelength of 0.57 centimetre after the subtraction of a uniform background at a temperature of 2.735 K. The bright regions at the upper right and the dark regions at the lower left show the dipole asymmetry. The bright strip across the middle represents excess thermal emission from the Milky Way. To obtain the fluctuations on smaller angular scales, it is necessary to subtract both the dipole and the galactic contributions. The latter requires a good model for the radio emission from the Galaxy at the relevant wavelengths, for which astronomers possess only incomplete knowledge. Fortunately, the corrections at high galactic latitudes are not very large, and Figure 4B shows the final product after the subtraction. The patches of light and dark represent temperature fluctuations that amount to about one part in 100,000—not much higher than the accuracy of the measurements. Nevertheless, the statistics of the distribution of angular fluctuations appear different from random noise, and so the members of the COBE investigative team believe that they have found the first evidence for the departure from exact isotropy that theoretical cosmologists have long predicted must be there in order for galaxies and clusters of galaxies to condense from an otherwise structureless universe.

Apart from the small fluctuations discussed above (one part in 100,000), the observed cosmic microwave background radiation exhibits a high degree of isotropy, a

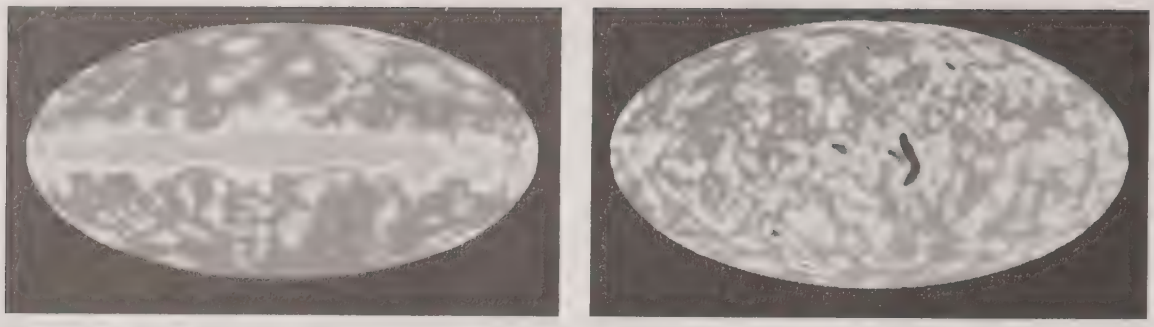

Figure 4: Images of measurements of intensity fluctuations of microwave background radiation transmitted by the Cosmic Background Explorer satellite. Figure 4A is an image showing how the intensity pattern appears in angular projection at a wavelength of 0.57 centimetre after subtracting a uniform background at 2.735 K. Figure 4B shows what remains after the subtraction. The light and dark patches represent shifts in temperature amounting to roughly one part per 100,000 (see text).

zeroth order fact that presents both satisfaction and difficulty for a comprehensive theory. On the one hand, it provides a strong justification for the assumption of homogeneity and isotropy that is common to most cosmological models. On the other hand, such homogeneity and isotropy are difficult to explain because of the "light-horizon" problem. In the context of the cosmic microwave background, the problem can be expressed as follows. Consider the background radiation coming to an observer from any two opposite sides of the sky. Clearly, whatever are the ultimate sources (hot plasma) of this radiation, the photons, traveling at the speed of light since their emission by the plasma, have only had time to reach the Earth now. The matter on one side of the sky could not have had time to have "communicated" with the matter on the other side (they are beyond each other's light horizon), so how is it possible (with respect to an observer in the right rest frame) that they "know" to have the same temperature to a precision approaching one part in 100,000? What accounts for the high degree of angular isotropy of the cosmic microwave background? Or, for that matter, for the large-scale distribution of galaxies? As will be seen below in the section *Cosmological models*, a mechanism called "inflation" may offer an attractive way out of this dilemma.

Intergalactic gas. At one time it was thought that large amounts of mass might exist in the form of gas clouds in the spaces between galaxies. One by one, however, the forms that this intergalactic gas might take were eliminated by direct observational searches until the only possible form that might have escaped early detection was a very hot plasma. Thus, there was considerable excitement and speculation when astronomers found evidence in the early 1970s for a seemingly uniform and isotropic background of hard X-radiation (photons with energies greater than 10^6 electron volts). There also was a diffuse background of soft X rays, but this had a patchy distribution and was definitely of galactic origin—hot gas produced by many supernova explosions inside the Galaxy. The hard X-ray background, in contrast, seemed to be extragalactic, and a uniform plasma at a temperature of roughly 10^8 K was a possible source. The launch in 1978 of an imaging X-ray telescope aboard the Einstein Observatory (the HEAO 2 satellite), however, showed that a large fraction of the seemingly diffuse background of hard X rays, perhaps all of it, could be accounted for by a superposition of previously unresolved point sources—*i.e.*, quasars and QSOs. Subsequent research demonstrated that the shape of the X-ray spectrum of these objects at low redshifts does not match that of the diffuse background. It is now thought that the residual effect arises from active galactic nuclei at high redshifts (greater than six) and that these objects underwent substantial evolution early in the history of the universe.

X-ray emission from hot intergalactic gas

Very hot gas that emits X rays at tens to hundreds of millions of kelvins does indeed reside in the spaces between galaxies in rich clusters, and the amount of this gas seems comparable to that contained in the visible stars of the galaxies; however, because rich clusters are fairly rare in the universe, the total amount of such gas is small compared to the total mass contained in the stars of all galaxies. Moreover, an emission line of iron can frequently be detected in the X-ray spectrum, indicating that the intracluster gas has undergone nuclear processing inside stars and is not of primordial origin.

About 70 percent of the X-ray clusters show surface brightnesses that are smooth and single-peaked, indicative of distributions of hot gas that rest in quasi-hydrostatic equilibrium in the gravitational potentials of the clusters. Analysis of the data in the better-resolved systems allows astronomers to estimate the total amount of gravitating mass needed to offset the expansive pressure (proportional to the density times the temperature) of the X-ray-emitting gas. These estimates agree with the conclusions from optical measurements of the motions of the member galaxies that galaxy clusters contain about 10 times more dark matter than luminous matter (see below).

About half of the X-ray clusters with single-peaked distributions have bright galaxies at the centres of the emission. The high central densities of the gas imply radiative cooling times of only 10^9 years or so. As the gas cools, the central galaxy draws the material inward at inferred rates that often exceed 100 solar masses per year. The ultimate fate of the accreted gas in the "cooling flow" remains unclear.

Another exciting discovery has been the detection of large clouds of atomic hydrogen gas in intergalactic space unassociated with any known galaxies. These clouds show themselves as unusual absorption lines in the Lyman-alpha transition of atomic hydrogen when they lie as foreground objects to distant quasars. In a few cases they can be mapped by radio techniques at the spin-flip transition of atomic hydrogen (redshifted from the rest wavelength of 21 centimetres). From the latter studies, some astronomers have inferred that the clouds exist in highly flattened forms ("pancakes") and may contain up to 10^{14} solar masses of gas. In one interpretation these structures are the precursors to large clusters of galaxies (see below).

Low-energy neutrinos. Another hypothesized component of the Cosmos is a universal sea of very low-energy neutrinos. Although nearly impossible to detect by direct means, the existence of this sea has a strong theoretical basis. This basis rests with the notion that a hot big bang would produce not only a primeval fireball of electromagnetic radiation but also enormous numbers of neutrinos and antineutrinos (both referred to in cosmological discussions as neutrinos for brevity's sake). Estimates suggest that every cubic metre of space in the universe contains about 10^8 low-energy neutrinos. This number considerably exceeds the cosmological density of atomic nuclei (mostly hydrogen) obtained by averaging the known matter in the universe over scales of hundreds of millions of light-years. The latter density amounts to less than one particle per cubic metre of space. Nevertheless, because neutrinos interact with matter only weakly (they do not, for example, emit electromagnetic radiation), they can be detected experimentally by sophisticated instruments only if they have relatively high energies (such as the neutrinos

from the Sun or from supernova explosions). The very low-energy neutrinos of cosmological origin cannot be observed by any conventional means known at present.

Such low-energy neutrinos, nonetheless, attracted considerable astronomical interest during the late 1970s because experiments conducted in the Soviet Union and the United States suggested, contrary to the prevailing belief in particle physics, that neutrinos may possess a nonzero rest mass. Even if the rest mass were very small—say, 10,000 times smaller than the rest mass of the electron, the lightest known particle of matter—the result could be of great potential importance because neutrinos, being so relatively abundant cosmologically, could then be the dominant source of mass in the universe. Unfortunately, later experiments cast doubts on the conclusions of the earlier findings, and theoretical investigations of "massive neutrinos" as the dark matter in the universe turned up as many new difficulties to be explained as possible solutions to old problems. On the other hand, if the solution to the solar-neutrino problem turns out to depend on the existence of neutrino oscillations, massive-neutrino cosmologies may well make a (partial) comeback.

Gravitational waves. Superficially, there are many similarities between gravity and electricity; for example, Newton's law for the gravitational force between two point masses and Coulomb's law for the electric force between two point charges both vary as the inverse square of the separation distance. Yet, in James Clerk Maxwell's theory for electromagnetism, accelerated charges emit signals (electromagnetic radiation) that travel at the speed of light, whereas in Newton's theory of gravitation accelerated masses transmit information (action at a distance) that travels at infinite speed. This dichotomy is repaired by Einstein's theory of gravitation, wherein accelerated masses also produce signals (gravitational waves) that travel only at the speed of light. And, just as electromagnetic waves can make their presence known by the pushing to and fro of electrically charged bodies, so can gravitational waves be detected, in principle, by the tugging to and fro of massive bodies. However, because the coupling of gravitational forces to masses is intrinsically much weaker than the coupling of electromagnetic forces to charges, the generation and detection of gravitational radiation are much more difficult than those of electromagnetic radiation. Indeed, since the time of Einstein's invention of general relativity in 1916, there has yet to be a single instance of the detection of gravitational waves that is direct and undisputed.

There are, however, some indirect pieces of evidence that accelerated astronomical masses do emit gravitational radiation. The most convincing concerns radio-timing observations of a pulsar located in a binary star system with an orbital period of 7.75 hours. This object, discovered in 1974, has a pulse period of about 59 milliseconds that varies by about one part in 1,000 every 7.75 hours. Interpreted as Doppler shifts, these variations imply orbital velocities on the order of $^1/_{1000}$ the speed of light. The nonsinusoidal shape of the velocity curve with time allows a deduction that the orbit is quite noncircular (indeed, an ellipse of eccentricity 0.62 whose long axis precesses in space by 4.2° per year). It is now believed that the system is composed of two neutron stars, each having a mass of about 1.4 solar masses, with a semimajor axis separation of only 2.8 solar radii. According to Einstein's theory of general relativity, such a system ought to be losing orbital energy through the radiation of gravitational waves at a rate that would cause them to spiral together on a time scale of about 3×10^8 years. The observed decrease in the orbital period in the years since the discovery of the binary pulsar does indeed indicate that the two stars are spiraling toward one another at exactly the predicted rate.

Binary pulsar as a possible source of gravitational radiation

The implosion of the core of a massive star to form a neutron star prior to a supernova explosion, if it takes place in a nonspherically symmetric way, ought to provide a powerful burst of gravitational radiation. Simple estimates yield the release of a fraction of the mass-energy deficit, roughly 10^{53} ergs, with the radiation primarily coming out at wave periods between the vibrational period of the neutron star, approximately 0.3 millisecond, and the gravitational-radiation damping time, about 300 milliseconds.

A cosmic background of gravitational waves is a possibility that has sometimes been discussed. Such a background might be generated if the early universe expanded in a chaotic fashion rather than in the smooth homogeneous fashion that it is currently observed to do. The energy density of the gravitational waves produced, however, is unlikely to exceed the energy density of electromagnetic radiation, and each graviton (the gravitational analogue of the photon) would be susceptible to the same cosmological redshift by the expansion of the universe. A roughly thermal distribution of gravitons at a present temperature of about 1 K would be undetectable by foreseeable technological developments in gravitational-wave astronomy.

Dark matter. Numerous candidates for the dark matter component in the halos of galaxies and clusters of galaxies have been proposed over the years, but no successful detection of any of them has yet occurred. If the dark matter is not made of the same material as the nuclei of ordinary atoms, then it may consist of exotic particles capable of interacting with ordinary matter only through the gravitational and weak nuclear forces. The latter property lends these hypothetical particles the generic name WIMPs, after weakly interacting massive particles. Even if WIMPs bombarded each square centimetre of the Earth at a rate of one per second (as they would do if they had, for example, individually 100 times the mass of a proton and collectively enough mass to "close" the universe; see below), they would then still be extremely difficult—though not impossible—to detect experimentally.

Another possibility is that the dark matter is (or was) composed of ordinary matter at a microscopic level but is essentially nonluminous at a meaningful astronomical level. Examples would be brown dwarfs (starlike objects too low in mass to fuse hydrogen in their interiors), dead white dwarfs, neutron stars, and black holes. If the objects are only extremely faint (*e.g.,* brown dwarfs), they can eventually be found by very sensitive searches, perhaps at near-infrared wavelengths. On the other hand, if they emit no light at all, then other strategies will be needed to find them—for example, to search halo stars for evidence of "microlensing" (*i.e.,* the temporary amplification of the brightness of background sources through the gravitational bending of their light rays).

Large-scale structure and expansion of the universe

Hubble inferred a uniformity in the spatial distribution of galaxies through number counts in deep photographic surveys of selected areas of the sky. This inference applies only to scales larger than several times 10^8 light-years. On smaller scales, galaxies tend to bunch together in clusters and superclusters, and Hubble deliberately avoided the more conspicuous examples in order not to bias his results. This clustering did excite debate among both observers and theorists in the earliest discussions of cosmology, particularly over the largest dimensions where there are still appreciable departures from homogeneity and over the ultimate cause of the departures. In the 1950s and early 1960s, however, attention tended to focus on homogeneous cosmological models because of the competing ideas of the big bang and steady state scenarios. Only after the discovery of the cosmic microwave background—which, together with the successes of primordial nucleosynthesis, signaled a clear victory for the hot big bang picture—did the issue of departures from homogeneity in the universe again attract widespread interest.

From a more pragmatic point of view, clusters and groups of galaxies are important to cosmological studies because they are useful in establishing the extragalactic distance scale. A fundamental problem that recurs over and over again in astronomy is the determination of the distance to an object. Individual stars in star clusters and associations provide an indispensable tool in gauging distances within the Galaxy. The brightest stars—in particular the brightest variable stars among the so-called Cepheid class—allow the distance ladder to be extended to the nearest galaxies;

Distance determinations

but at distances much larger than 10^7 light-years individual stars become too difficult to resolve, at least from the ground, and astronomers have traditionally resorted to other methods (see GALAXIES).

CLUSTERING OF GALAXIES

Types of clusters

Clusters of galaxies fall into two morphological categories: regular and irregular. The regular clusters show marked spherical symmetry and have a rich membership. Typically, they contain thousands of galaxies, with a high concentration toward the centre of the cluster. Rich clusters, such as the Coma cluster, are deficient in spiral galaxies and are dominated by ellipticals and S0s. The irregular clusters have less well-defined shapes, and they usually have fewer members, ranging from fairly rich systems such as the Hercules cluster to poor groups that may have only a few members. Galaxies of all types can be found in irregular clusters: spirals and irregulars, as well as ellipticals and S0s. Most galaxies are to be found not in rich clusters but in loose groups. The Galaxy belongs to one such loose group—the Local Group.

The Local Group. The Local Group contains seven reasonably prominent galaxies and perhaps another two dozen less conspicuous members. The dominant pair in the group is the Milky Way and Andromeda, both giant spirals of Hubble type Sb and luminosity class II. The distance to the Andromeda system was first measured by Hubble, but his estimate was too low by a factor of two because astronomers at that time did not recognize the distinction between variable stars belonging to Population II (like those studied by Shapley) and Population I (those studied by Hubble). Another spiral in the Local Group—M33, Hubble type Sc and luminosity class III—is notable, but the rest are intermediate to dwarf systems, either irregulars or ellipticals. Most of the mass of the Local Group is associated with the Milky Way and Andromeda, and with a few exceptions the smaller systems tend to congregate about one or the other of these galaxies. The size of the Local Group is therefore larger only by about 50 percent than the 2×10^6 light-years separating the Milky Way system and the Andromeda galaxy, and the centre of mass lies roughly halfway between these two giants.

The Andromeda galaxy is one of the few galaxies in the universe that actually has a velocity of approach with respect to the centre of the Galaxy. If this approach results from the reversal by the mutual gravitational attraction of a former recession, then the total mass of the Local Group probably amounts to a few times 10^{12} solar masses. This is greater than the mass inferred for the optically visible parts of the galaxies and is another manifestation of the dark matter problem.

Neighbouring groups and clusters. Beyond the fringes of the Local Group lie many similar small groups. The

The M81 group

best studied of these is the M81 group, whose dominant galaxy is the spiral galaxy M81. Much like the Andromeda and Milky Way systems, M81 is of Hubble type Sb and luminosity class II. The distance to M81, as well as to the outlying galaxy NGC 2403, can be determined from various stellar calibrators to be at a distance of 10^7 light-years. It is not known whether NGC 2403 and its companion NGC 2366 are truly bound to M81 or whether they are an independent pair seen by chance to lie near the M81 group. If they are bound to M81, then a measurement of their velocity along the line of sight relative to that of M81 yields, by an argument similar to that used for the Andromeda and Milky Way galaxies, an estimate of the gravitating mass of M81. This estimate equals 2×10^{12} solar masses and exceeds by an order of magnitude what is deduced from measurements of the rotation curve of M81 inside its optically visible disk.

The M81 group also has a few normal galaxies with classifications similar to those of galaxies in the Local Group, and it was noticed by some astronomers that the linear sizes of the largest H II regions (which are illuminated by many OB stars) in these galaxies had about the same intrinsic sizes as their counterparts in the Local Group. This led Allan Sandage and the German chemist and physicist Gustav Tammann to the (controversial) technique of using the sizes of H II regions as a distance indicator, because a measurement of their angular sizes, coupled with knowledge of their linear sizes, allows an inference of distance.

This method can be used, for example, to obtain the distance to the M101 group, whose dominant galaxy M101 is a supergiant spiral—the closest system of Hubble type Sc and luminosity class I. Since Sc I galaxies are the most luminous spiral galaxies, with very large H II regions strung out along their spiral arms, determining the distance to M101 is a crucial step in obtaining the absolute sizes of the giant H II regions of these important systems. The sizes of the H II regions in the companion galaxies of M101 compared with the calibrated values for nearby galaxies of the same class yield a distance to the M101 group of approximately 2×10^7 light-years.

Having calibrated the sizes of the giant H II regions in M101, Sandage and Tammann could then obtain the distances to 50 field Sc I galaxies. Once this had been done, it became possible to measure the absolute brightnesses of Sc I galaxies, and it was ascertained that all such systems have nearly the same luminosity. Since Sc I galaxies like M101 or M51 can be recognized on purely morphological grounds (well-organized spiral structure with massive arms dominated by giant H II regions), they can now be used as "standard candles" to help measure the distances to irregular clusters that contain such galaxies (*e.g.*, the Virgo cluster containing the Sc I galaxy M100).

Virgo and Coma clusters

The Virgo cluster is the closest large cluster and is located at a distance of about 5×10^7 light-years in the direction of the constellation Virgo. About 200 bright galaxies reside in the Virgo cluster, scattered in various subclusters whose largest concentration (near the famous system M87) is about 5×10^6 light-years in diameter. Of the galaxies in the Virgo cluster, 68 percent are spirals, 19 percent are ellipticals, and the rest are irregulars or unclassified. Although spirals are more numerous, the four brightest galaxies are giant ellipticals, among them M87. Calibration of the absolute brightnesses of these giant ellipticals allows a leap to the distant regular clusters.

The nearest rich cluster containing thousands of systems, the Coma cluster, lies about seven times farther than the Virgo cluster in the direction of the constellation Coma Berenices. The main body of the Coma cluster has a diameter of about 2.5×10^7 light-years, but enhancements above the background can be traced out to a supercluster of a diameter of about 2×10^8 light-years. Ellipticals or S0s constitute 85 percent of the bright galaxies in the Coma cluster; the two brightest ellipticals in Coma are located near the centre of the system and are individually more than 10 times as luminous as the Andromeda galaxy. These galaxies have a swarm of smaller companions orbiting them and may have grown to their bloated sizes by a process of "galactic cannibalism" like that hypothesized to explain the supergiant elliptical cD systems (see above).

The spatial distribution of galaxies in rich clusters such as the Coma cluster closely resembles what one would expect theoretically for a bound set of bodies moving in the collective gravitational field of the system. Yet, if one measures the dispersion of random velocities of the Coma galaxies about the mean, one finds that it amounts to almost 900 km/sec. For a galaxy possessing this random velocity along a typical line of sight to be gravitationally bound within the known dimensions of the cluster requires Coma to have a total mass of about 5×10^{15} solar masses. The total luminosity of the Coma cluster is measured to be about 3×10^{13} solar luminosities; therefore, the mass-to-light ratio in solar units required to explain Coma as a bound system exceeds by an order of magnitude what can be reasonably ascribed to the known stellar populations. A similar situation exists for every rich cluster that has been examined in detail. This dark matter problem for rich clusters was known to the Swiss astronomer Fritz Zwicky as early as 1933. The discovery of X-ray-emitting gas in rich clusters has alleviated the dynamic problem by a factor of about two, but a substantial discrepancy remains.

Superclusters. In 1932 Harlow Shapley and Adelaide Ames introduced a catalog that showed the distributions of galaxies brighter than 13th magnitude to be quite different north and south of the plane of the Galaxy. Their study was the first to indicate that the universe might contain

substantial regions that departed from the assumption of homogeneity and isotropy. The most prominent feature in the maps they produced in 1938 was the Virgo cluster, though already apparent at that time were elongated appendages that stretched on both sides of Virgo to a total length exceeding 5×10^7 light-years. This configuration is the kernel of what came to be known later—through the work of Erik Holmberg, Gérard de Vaucouleurs, and George O. Abell—as the Local Supercluster, a flattened collection of about 100 groups and clusters of galaxies including the Local Group. The Local Supercluster is centred approximately on the Virgo cluster and has a total extent of roughly 2×10^8 light-years. Its precise boundaries, however, are difficult to define inasmuch as the local enhancement in numbers of galaxies above the cosmological average in all likelihood just blends smoothly into the background.

The Local Supercluster

Also apparent in the Shapley-Ames maps were three independent concentrations of galaxies, separate superclusters viewed from a distance. Astronomers now believe superclusters fill perhaps 10 percent of the volume of the universe. Most galaxies, groups, and clusters belong to superclusters, the space between superclusters being relatively empty. The dimensions of superclusters range up to a few times 10^8 light-years. For larger scales the distribution of galaxies is essentially homogeneous and isotropic—that is, there is no evidence for the clustering of superclusters. This fact can be understood by recognizing that the time it takes a randomly moving galaxy to traverse the long axis of a supercluster is typically comparable to the age of the universe. Thus, if the universe started out homogeneous and isotropic on small scales, there simply has not been enough time for it to become inhomogeneous on scales much larger than superclusters. This interpretation is consistent with the observation that superclusters themselves look dynamically unrelaxed—that is, they lack the regular equilibrium shapes and central concentrations that typify systems well mixed by several crossings.

Statistics of clustering. The description of galaxy clustering given above is qualitative and therefore open to a charge of faulty subjective reasoning. To remove human biases it is possible to take a statistical approach, a path pioneered by the American statisticians Jerzy Neyman and Elizabeth L. Scott and extended by H. Totsuji and T. Kihara in Japan and by P.J.E. Peebles and his coworkers in the United States. Their line of attack begins by considering the correlation of the angular positions of galaxies in the northern sky surveyed by C.D. Shane and C.A. Wirtanen of Lick Observatory, Mount Hamilton, Calif. If the intrinsic distribution in the direction along the line of sight is assumed to be similar to that across it, then it is possible to derive from the analysis the two-point correlation function that expresses the joint probability for finding two galaxies in certain positions separated by a distance r. Of special interest is the enhancement in the probability above a random distribution of locations well represented, up to scales of about 5×10^7 light-years, as a simple power law, $(r/r_0)^{-1.8}$, with r_0 equal to about 2×10^7 light-years. Beyond 5×10^7 light-years, the enhancement drops more quickly with distance than $r^{-1.8}$, but the exact way it does this is somewhat controversial.

To summarize, then, when one knows a galaxy to be present, there is a considerable statistical enhancement in the likelihood that other galaxies will be near it for distances of 5×10^7 light-years or less, whereas at much larger distances the probability drops off to the expectation for a purely random distribution in space. This result provides a quantitative expression for the phenomenon of galaxy clustering. A similar power-law representation seems to hold for the correlation of galaxy clusters; this provides empirical evidence for the phenomenon of superclustering.

In addition to angular positions, it is possible to derive empirical information about the large-scale distribution of galaxies in the direction along the line of sight by examining the redshifts of galaxies under the assumption that a larger redshift implies a greater distance in accordance with Hubble's law. A number of groups have carried out such a program, some in fairly restricted areas of the sky and others over larger regions but to shallower depths. A primary finding of such surveys is the existence of huge holes and voids, regions of space measuring hundreds of millions of light-years across where galaxies seem notably deficient or even totally absent. The presence of holes and voids forms, in some sense, a natural complement to the idea of superclusters, but the surprising result is the degree of the density contrast between the large-scale regions where galaxies are found and those where they are not (Figure 5).

Immense holes and voids in space

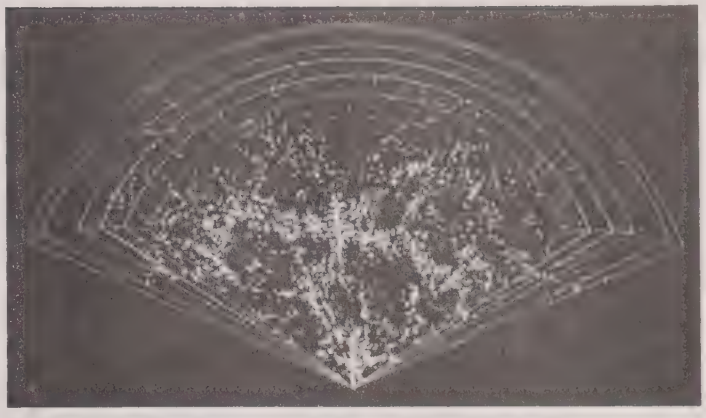

Figure 5: A two-dimensional representation of a three-dimensional "map" of galaxies distributed on the surfaces of what are thought to be enormous bubblelike voids measuring approximately 60,000,000 to 150,000,000 light-years across. The pie-shaped segment of the sky shown here contains about 1,000 galaxies, all located within 300,000,000 light-years from the Earth. The Coma cluster of galaxies, lying near the middle of the segment, seems to occur where several voids intersect.
M.J. Geller and J.P. Huchra, Smithsonian Astrophysical Observatory

GRAVITATIONAL THEORIES OF CLUSTERING

The fact that gravitation affects all masses may explain why the astronomical universe, although not uniform, contains structure. This natural idea, which is the basis of much of the modern theoretical work on the problem, had already occurred to Newton in 1692. Newton wrote to the noted English scholar and clergyman Richard Bentley:

> It seems to me, that if the matter of our Sun & Planets & all ye matter in the Universe was evenly scattered throughout all the heavens, & every particle had an innate gravity towards all the rest & the whole space throughout wch [sic] this matter was scattered was but finite: the matter on ye outside of this space would by its gravity tend towards all ye matter on the inside & by consequence fall down to ye middle of the whole space & there compose one great spherical mass. But if the matter was evenly diffused through an infinite space, it would never convene into one mass but some of it convene into one mass & some into another so as to make an infinite number of great masses scattered at great distances from one to another throughout all yt infinite space. And thus might ye Sun and Fixt stars be formed supposing the matter were of a lucid nature.

Modes of gravitational instability. It was the English physicist and mathematician Sir James Jeans who in 1902 first provided a quantitative criterion for the picture of gravitational instability speculated on by Newton. Jeans considered the idealized initial state of a homogeneous static gas of infinite extent and uniform temperature and asked under what conditions the compressed portions of a small sinusoidal fluctuation would continue to contract gravitationally and become denser and denser (eventually to form galaxies and stars presumably) rather than re-expand because of the increased internal pressure. He found that for gravitational instability to occur the wavelength of the density fluctuation had to exceed a certain critical value, now called the Jeans length, which is proportional to the square root of the ratio of temperature to density.

Two new considerations enter to modify the picture in a universe that begins with a hot big bang: the expansion of the background and the coexistence with matter of a thermal radiation field. The expansion of the background causes the dense portions of unstable small fluctuations

to grow much more slowly, at least at first, than the static Jeans theory—as a power of time rather than as an exponential. The thermal radiation field causes greater complications.

First, the existence of a component in the universe other than ordinary matter, radiation, means that one has to specify—particularly in the early stages of the expansion when the energy density of radiation dominates that of matter—whether the radiation field fluctuates together with matter or whether it maintains a uniform level inside which matter fluctuates. Density fluctuations of the first type are called adiabatic perturbations, and those of the second type isothermal (isocurvature) perturbations (because the temperature of the radiation field remains uniform in space and the matter temperature locally equals that of the radiation when they are well coupled).

Adiabatic and isothermal perturbations

In the early universe when the radiation temperature was high and matter existed as a highly ionized plasma, neither adiabatic nor isothermal fluctuations could grow, because the intense radiation field resisted compression and, through its strong coupling to ionized matter, prevented the latter also from contracting relative to the overall expansion of the universe. Indeed, the tendency for the excess radiation in the compressed regions of adiabatic fluctuations to try to diffuse out of such regions implies that such fluctuations tend to decay. Therefore, given an arbitrary initial spectrum of adiabatic fluctuations, only those with a large enough scale can survive the decay for the age of the universe up to that point.

Decoupling between ordinary matter and radiation occurs when the temperature drops low enough for free (hydrogen) ions and electrons to recombine. When electrons become attached to atoms, they have a much smaller cross section for interaction with photons than when they were free. This occurs for reasonable cosmological models at a temperature of about 4,000 K. At this time, by coincidence (but perhaps ultimately one of great physical significance), the energy density also begins to drop below the rest-energy density of matter, and the universe turns from being radiation-dominated to being matter-dominated. Past the decoupling epoch, the density fluctuations of the type previously labeled isothermal can grow if they satisfy the original Jeans criterion, whereas those previously labeled adiabatic can grow only if they have survived the prior epoch of damping. Calculations indicate that the smallest unstable fragment of the former type has a mass comparable to that of a globular cluster, while that of the latter type has a mass comparable to that of a giant galaxy or of a large cluster of galaxies, depending on various assumptions.

Possible forms of the hypothesized hidden mass

Among these assumptions is the choice of the form of the dark matter or hidden mass. If the hidden mass is not ordinary matter but instead is contained in exotic forms of elementary particles whose properties have yet to be deciphered, then one needs to specify if and when this hidden mass decouples from the thermal radiation field. Two extremes are often considered: "warm" dark matter and "cold" dark matter. Warm dark matter is typified by such hypothetical particles as neutrinos that have small but nonzero rest mass, which decouple relatively early from the radiation field. Particles of this sort stream freely (nearly at the speed of light in the early universe) and erase initial fluctuations of all scale smaller than a critical coherence length (analogous to but larger than the critical scale introduced by photons for adiabatic fluctuations), above which self-gravity can finally cause growth (when the neutrinos are moving much less rapidly). Cold dark matter is typified by particles that interact only weakly with radiation and ordinary matter and that have sufficient rest mass so as always to possess random thermal motions much less than the speed of light at any stage relevant to the problem of galaxy formation. Density fluctuations of such particles can grow in a fashion similar to that described for isothermal fluctuations of ordinary matter after decoupling; therefore, on the scale of galaxies and larger groups, cold dark matter possesses no coherence length. In either picture, warm or cold, the dark component of the universe supposedly forms a lumpy background into whose concentrations ordinary matter falls eventually to produce galaxies and stars.

Top-down and bottom-up theories. The scenarios described in the previous subsection turn out, in the extremes, to lead to two different pictures for the origin of large-scale structure in the universe, which can be given the labels "top-down" and "bottom-up." In top-down theories the regions with the largest scale sizes, comparable to superclusters and clusters, collapse first, yielding flat gaseous "pancakes" of ordinary matter (a description coined by the primary proponent of this theory, the physicist Yakov B. Zeldovich of Russia) from which galaxies condense. In bottom-up theories the regions with the smallest scale sizes, comparable to galaxies or smaller, form first, giving rise to freely moving entities that subsequently aggregate gravitationally (perhaps by a hierarchal process) to produce clusters and superclusters of galaxies. Adiabatic fluctuations of ordinary matter tend to yield a top-down picture, and isothermal fluctuations a bottom-up picture. When hidden mass is added to the calculations, warm dark matter tends to give a top-down picture, and cold dark matter a bottom-up picture.

Origin of large-scale cosmic structures

To make comparisons with observational data, the spectrum (dependence of amplitudes with size scale) of the initial fluctuations are needed as input to numerical simulations on a computer to follow the subsequent growth of structure. The shape of the spectrum is specified by heuristic arguments given first by Zeldovich and the American cosmologist Edward R. Harrison, and the results were later rederived from a first principles calculation of a quantum origin of the universe involving cosmic inflation (see below). Workers must use, however, measurements of the anisotropy of the cosmic microwave background to obtain (or set limits on) the absolute starting amplitudes. When this is done and models are computed, it is found that top-down theories tend to give a better but still imperfect account of the observed spatial distributions (flattened superclusters and large holes and voids) and streaming motions of galaxies. Unfortunately, cluster formation and galaxy formation take place at a redshift z less than 1, too recently relative to the present epoch to be compatible with the observational data. The measurements of the anisotropies of the cosmic microwave background severely limit the amount of power that can exist in the starting adiabatic perturbations, and so the growth to observed structures takes too long to complete. Moreover, neutrinos with their large coherence length probably cannot explain the hidden mass that is inferred to reside in the dark halos of individual galaxies.

Bottom-up theories that include cold dark matter can yield objects with the proper masses (*i.e.,* dark halos), density profiles, and angular momenta to account for the observed galaxies, but they fail to explain the largest-scale structures (on the order of a few times 10^8 light-years) seen in the clustering data. A possible escape from this difficulty lies in the suggestion that the distribution of galaxies (made mostly of ordinary matter) may not trace the distribution of mass (made mostly of cold dark matter). This scheme, called biased galaxy formation, may have a physical basis if it can be argued that galaxies form only from fluctuations that exceed a certain threshold level. Local upward fluctuations in density on a small scale have a better chance to exceed the threshold if they happen to lie in a large region that has somewhat higher than average densities. This bias then produces galaxies with positions that correlate on a large scale better than the underlying distribution of dark matter whose gravitational clustering has no such threshold effect. Unfortunately, counter simulations show that no amount of biasing can reproduce both the large-scale spatial structure and the magnitude of the observed large-scale streaming motions.

Biased galaxy formation

On the problem of the formation of galaxies and large-scale structure by purely gravitational means, therefore, cosmologists face the following dilemma. The universe in the large appears to require aspects of both top-down and bottom-up theories. Perhaps this implies that the hidden mass consists of roughly equal mixtures of warm dark matter and cold dark matter, but adopting such a solution seems rather artificial without additional supporting evidence.

UNORTHODOX THEORIES OF CLUSTERING AND GALAXY FORMATION

Given the somewhat unsatisfactory state of affairs with gravitational theories for the origin of large-scale structure in the universe, some cosmologists have abandoned the orthodox approach altogether and have sought alternative mechanisms. One of the first to be considered was primordial turbulence. This idea enjoys little current favour for a variety of reasons, the most severe being the following. Because it tends to decay over time, turbulence of a magnitude sufficient to cause galaxy formation after decoupling would have had to be much larger during earlier epochs. This seems both unlikely and unnatural. Too delicate a balance is required for primordial turbulence to produce galaxies rather than, say, black holes.

Another suggestion is that energetic galactic explosions due to the formation of a first wave of massive stars may have compressed large shells of intergalactic gas that subsequently became the sites for further galaxy formation and more explosions. Such a picture is attractive because it predicts large holes and voids with galaxies at the interfaces, but it does not avoid the criticism that a "seed" galaxy needs to be formed at the centre of each shell by some other process. If such a process exists, why should it not be the dominant mechanism?

The notion of cosmic strings

Finally, there is a suggestion that galaxy and cluster formation might take place by accretion around "cosmic strings." Cosmic strings, long strands or loops of mass-energy, are a consequence of some theories of elementary particle physics. They are envisaged to arise from phase transitions in the very early universe in a fashion analogous to the way faults can occur in a crystal that suffers dislocations because of imperfect growth from, say, a liquid medium. The dynamic properties of cosmic strings are imperfectly understood, but arguments exist that suggest they may give a clustering hierarchy similar to that observed for galaxies. Unfortunately, the same particle physics that produces cosmic strings also produces magnetic monopoles (isolated magnetic charges), whose possible abundance in the universe can be constrained by observations and experiments to lie below very low limits. Particle physicists like to explain the absence of magnetic monopoles in the Cosmos by invoking for the very early universe the mechanism of inflation (see below). The same mechanism would also inflate away cosmic strings.

In summary, it can be seen that mechanisms alternative to the growth of small initial fluctuations by self-gravitation all have their own difficulties. Most astronomers hope some dramatic new observation or new idea may yet save the gravitational instability approach, whose strongest appeal has always been the intuitive notion that the force that dominates the astronomical universe, gravity, will automatically promote the growth of irregularities. But, until a complete demonstration is provided, the lack of a simple convincing picture of how galaxies form and cluster will remain one of the prime failings of the otherwise spectacularly successful hot big bang theory.

THE EXTRAGALACTIC DISTANCE SCALE AND HUBBLE'S CONSTANT

It was noted earlier that the galaxies in the Virgo cluster had an average recession velocity v (as measured by their redshift) of roughly 1,000 km/sec with respect to the Local Group. If the distance r to the Virgo cluster is 5×10^7 light-years and if the Virgo galaxies can be assumed to be far enough away to partake in the general Hubble flow, then the application of the Hubble law, $v = H_0 r$, yields Hubble's constant as $H_0 = 20$ km/sec per million light-years. The reciprocal of Hubble's constant is called the Hubble time; for the value given above, $H_0^{-1} = 1.5 \times 10^{10}$ years.

The Hubble time

The most naive interpretation for the Hubble time is that of a free expansion of the universe, wherein a Hubble time ago the distant galaxies started receding from one another (in particular, from the Milky Way system), reaching a distance $r = vH_0^{-1}$ in time H_0^{-1} if they fly away at speed v, the fastest receding galaxies getting the farthest away. Rearranging terms yields the Hubble law $v = H_0 r$. The interpretation is naive in two respects: (1) it ignores the role of gravitation in slowing down the expansion, so that Hubble's "constant" does not always have the value it does at the present epoch; and (2) it overlooks the part played by gravitation in regulating the global structure of space-time, so that the interpretation of the "velocity" v and "distance" r is modified when distances or redshifts approach values such that v given by the above formula becomes comparable to or exceeds the speed of light. Nevertheless, as will be seen in the discussion of relativistic cosmologies below, the Hubble time does provide a useful rough estimate for the age of the universe.

The exact value of Hubble's constant is an issue of great controversy among astronomers. Modern estimates for H_0 range from 15 to 30 km/sec per million light-years. The source of the discrepancy lies partly in the interpretation of the amount of distortion superimposed atop a pure Hubble flow by the gravitational effects of the Local Supercluster in which the Local Group and the Virgo cluster are embedded and partly in the different calibrators used or emphasized by different workers for the distances to various extragalactic objects.

To avoid the first complication, the interpretation of the velocity field in the Local Supercluster, it is possible to examine the redshift-distance relation implied by Sandage's and Tammann's study of 50 Sc I galaxies. There is little controversy that these distant galaxies do empirically satisfy the idealized linear relationship of the Hubble law. The faintest galaxies in the sample have recession velocities of 9,000 km/sec, and, if they lie at the calibrated distance of 600 million light-years, then $H_0 = 15$ km/sec per million light-years, the same value as Sandage and Tammann derived from their study of the Virgo cluster. Unfortunately, many workers do not accept the determination of Sandage and Tammann of the distances to the nearest Sc I galaxies (in particular, M101). They regard as suspect the technique using the sizes of H II regions as a distance indicator. These astronomers advocate using the relationship found to exist between the luminosity L of a spiral galaxy and the velocity V of its (flat) rotation curve, L proportional to V^4, as a basis for measuring extragalactic distances, and they obtain values for H_0 that lie on the high end of the range cited above.

As discussed earlier, the classical means of obtaining the distance to the Virgo cluster (a crucial accomplishment) relies on a bootstrap operation to pull the observer up the extragalactic distance ladder one step at a time. The problem with the method is that errors at one level propagate to the next. For this reason, some astronomers prefer using supernova explosions, which can be seen at great distances, to get from the Local Group to the Virgo cluster in one jump. Two basic methods have been developed, one using supernovas of type Ia and the other employing supernovas of type II.

Type Ia supernovas are believed to arise in interacting binaries from the thermonuclear explosion of a carbon-oxygen white dwarf pushed beyond the Chandrasekhar limit by mass transfer from a neighbouring companion star. In the process a fixed amount of radioactive nickel-56 is believed to be produced, whose subsequent decay into cobalt-56 and then to stable iron-56 is thought to power the entire light curve in these events. As a consequence of the uniformity of the underlying processes, type Ia supernovas serve, in principle, as excellent "standard candles" to obtain extragalactic distances. In practice, the uniformity of the underlying conditions has been questioned as being controversial.

Type II supernovas arise when evolved massive stars undergo core collapse, a partial rebound, and an expulsion of the (hydrogen-rich) envelope. Except for a scale factor, the shape of the subsequent light curve allows astronomers to infer a changing size for the rapidly expanding atmosphere. The scale can be obtained by measuring the Doppler shift (yielding the velocity, or time-rate of change of the radius, in kilometres per second) of the same layers of gas. Once the absolute size has been fixed, the absolute brightness can be deduced.

From the deduced absolute brightness and the measured apparent brightness, the distance to the supernova can then be obtained. In principle, the method could be applied to supernovas of all types; in practice, good knowledge of the

opacities is needed to correct for the difference in depth observed in the spectral lines (for the Doppler-shift measurements) and in the continuum light (for the light-curve measurements). Such knowledge is reliable only when the composition of the atmospheric layers is rich in hydrogen.

The supernova techniques tend to yield values of H toward the low end of the range 15 to 30 km/sec per million light-years. For the sake of definiteness, this article adopts the value $H_0 = 20$ km/sec per million light-years, but it should be noted that uncertainties of the magnitude discussed still remain. The corollary of this warning is that the distances quoted for extragalactic objects also are uncertain by the same factor.

Cosmological models

EARLY COSMOLOGICAL IDEAS

Immediate issues that arise when anyone contemplates the universe at large are whether space and time are infinite or finite. And after many centuries of thought by some of the best minds, humanity has still not arrived at conclusive answers to these questions. Aristotle's answer was that the material universe must be spatially finite, for if stars extended to infinity, they could not perform a complete rotation around the Earth in 24 hours. Space must then itself also be finite because it is merely a receptacle for material bodies. On the other hand, the heavens must be temporally infinite, without beginning or end, since they are imperishable and cannot be created or destroyed.

Except for the infinity of time, these views came to be accepted religious teachings in Europe before the period of modern science. The most notable person to publicly express doubts about restricted space was the Italian philosopher-mathematician Giordano Bruno, who asked the obvious question that, if there is a boundary or edge to space, what is on the other side? For his advocacy of an infinity of suns and earths, he was burned at the stake in 1600.

In 1610 Kepler provided a profound reason for believing that the number of stars in the universe had to be finite. If there were an infinity of stars, he argued, then the sky would be completely filled with them and night would not be dark! This point was rediscussed by the astronomers Edmond Halley and Jean-Philippe-Loys de Chéseaux of Switzerland in the 18th century, but it was not popularized as a paradox until Heinrich Wilhelm Olbers of Germany took up the problem in the 19th century. The difficulty became potentially very real with Hubble's measurement of the enormous extent of the universe of galaxies with its large-scale homogeneity and isotropy. His discovery of the systematic recession of the galaxies provided an escape, however. At first people thought that the redshift effect alone would suffice to explain why the sky is dark at night—namely, that the light from the stars in distant galaxies would be redshifted to long wavelengths beyond the visible regime. The modern consensus is, however, that a finite age for the universe is a far more important effect. Even if the universe is spatially infinite, photons from very distant galaxies simply do not have the time to travel to the Earth because of the finite speed of light. There is a spherical surface, the cosmic event horizon (roughly 10^{10} light-years in radial distance from the Earth at the current epoch), beyond which nothing can be seen even in principle; and the number (roughly 10^{10}) of galaxies within this cosmic horizon, the observable universe, are too few to make the night sky bright.

When one looks to great distances, one is seeing things as they were a long time ago, again because light takes a finite time to travel to Earth. Over such great spans, do the classical notions of Euclid concerning the properties of space necessarily continue to hold? The answer given by Einstein was: No, the gravitation of the mass contained in cosmologically large regions may warp one's usual perceptions of space and time; in particular, the Euclidean postulate that parallel lines never cross need not be a correct description of the geometry of the actual universe. And in 1917 Einstein presented a mathematical model of the universe in which the total volume of space was finite yet had no boundary or edge. The model was based on his theory of general relativity that utilized a more generalized approach to geometry devised in the 19th century by the German mathematician Bernhard Riemann.

GRAVITATION AND THE GEOMETRY OF SPACE-TIME

The physical foundation of Einstein's view of gravitation, general relativity, lies on two empirical findings that he elevated to the status of basic postulates. The first postulate is the relativity principle: local physics is governed by the theory of special relativity. The second postulate is the equivalence principle: there is no way for an observer to distinguish locally between gravity and acceleration. The motivation for the second postulate comes from Galileo's observation that all objects—independent of mass, shape, colour, or any other property—accelerate at the same rate in a (uniform) gravitational field.

The principles of relativity and equivalence

Einstein's theory of special relativity, which he developed in 1905, had as its basic premises (1) the notion (also dating back to Galileo) that the laws of physics are the same for all inertial observers and (2) the constancy of the speed of light in a vacuum—namely, that the speed of light has the same value (3×10^{10} cm/sec) for all inertial observers independent of their motion relative to the source of the light. Clearly, this second premise is incompatible with Euclidean and Newtonian precepts of absolute space and absolute time, resulting in a program that merged space and time into a single structure, with well-known consequences. The space-time structure of special relativity is often called "flat" because, among other things, the propagation of photons is easily represented on a flat sheet of graph paper with equal-sized squares. Let each tick on the vertical axis represent one light-year (9.46×10^{17} cm) of distance in the direction of the flight of the photon, and each tick on the horizontal axis represent the passage of one year (3.16×10^7 sec) of time. The propagation path of the photon is then a 45° line because it flies one light-year in one year (with respect to the space and time measurements of all inertial observers no matter how fast they move relative to the photon).

Warping of space-time by gravitation

The principle of equivalence in general relativity allows the locally flat space-time structure of special relativity to be warped by gravitation, so that (in the cosmological case) the propagation of the photon over thousands of millions of light-years can no longer be plotted on a globally flat sheet of paper. To be sure, the curvature of the paper may not be apparent when only a small piece is examined, thereby giving the local impression that space-time is flat (*i.e.*, satisfies special relativity). It is only when the graph paper is examined globally that one realizes it is curved (*i.e.*, satisfies general relativity).

In Einstein's 1917 model of the universe, the curvature occurs only in space, with the graph paper being rolled up into a cylinder on its side, a loop around the cylinder at constant time having a circumference of $2\pi R$—the total spatial extent of the universe. Notice that the "radius of the universe" is measured in a "direction" perpendicular to the space-time surface of the graph paper. Since the ringed space axis corresponds to one of three dimensions of the actual world (any will do since all directions are equivalent in an isotropic model), the radius of the universe exists in a fourth spatial dimension (not time) which is not part of the real world. This fourth spatial dimension is a mathematical artifice introduced to represent diagrammatically the solution (in this case) of equations for curved three-dimensional space that need not refer to any dimensions other than the three physical ones. Photons traveling in a straight line in any physical direction have trajectories that go diagonally (at 45° angles to the space and time axes) from corner to corner of each little square cell of the space-time grid; thus, they describe helical paths on the cylindrical surface of the graph paper, making one turn after traveling a spatial distance $2\pi R$. In other words, always flying dead ahead, photons would return to where they started from after going a finite distance without ever coming to an edge or boundary. The distance to the "other side" of the universe is therefore πR, and it would lie in any and every direction; space would be closed on itself.

Fourth spatial dimension

Now, except by analogy with the closed two-dimensional surface of a sphere that is uniformly curved toward a

centre in a third dimension lying nowhere on the two-dimensional surface, no three-dimensional creature can visualize a closed three-dimensional volume that is uniformly curved toward a centre in a fourth dimension lying nowhere in the three-dimensional volume. Nevertheless, three-dimensional creatures could discover the curvature of their three-dimensional world by performing surveying experiments of sufficient spatial scope. They could draw circles, for example, by tacking down one end of a string and tracing along a single plane the locus described by the other end when the string is always kept taut in between (a straight line) and walked around by a surveyor. In Einstein's universe, if the string were short compared to the quantity R, the circumference of the circle divided by the length of the string (the circle's radius) would nearly equal $2\pi = 6.2837853\ldots$, thereby fooling the three-dimensional creatures into thinking that Euclidean geometry gives a correct description of their world. However, the ratio of circumference to length of string would become less than 2π when the length of string became comparable to R. Indeed, if a string of length πR could be pulled taut to the antipode of a positively curved universe, the ratio would go to zero. In short, at the tacked-down end the string could be seen to sweep out a great arc in the sky from horizon to horizon and back again; yet, to make the string do this, the surveyor at the other end need only walk around a circle of vanishingly small circumference.

To understand why gravitation can curve space (or more generally, space-time) in such startling ways, consider the following thought experiment that was originally conceived by Einstein. Imagine an elevator in free space accelerating upward, from the viewpoint of a woman in inertial space, at a rate numerically equal to g, the gravitational field at the surface of the Earth. Let this elevator have parallel windows on two sides, and let the woman shine a brief pulse of light toward the windows. She will see the photons enter close to the top of the near window and exit near the bottom of the far window because the elevator has accelerated upward in the interval it takes light to travel across the elevator. For her, photons travel in a straight line, and it is merely the acceleration of the elevator that has caused the windows and floor of the elevator to curve up to the flight path of the photons.

Let there now be a man standing inside the elevator. Because the floor of the elevator accelerates him upward at a rate g, he may—if he chooses to regard himself as stationary—think that he is standing still on the surface of the Earth and is being pulled to the ground by its gravitational field g. Indeed, in accordance with the equivalence principle, without looking out the windows (the outside is not part of his local environment), he cannot perform any local experiment that would inform him otherwise. Let the woman shine her pulse of light. The man sees, just like the woman, that the photons enter near the top edge of one window and exit near the bottom of the other. And just like the woman, he knows that photons propagate in straight lines in free space. (By the relativity principle, they must agree on the laws of physics if they are both inertial observers.) However, since he actually sees the photons follow a curved path relative to himself, he concludes that they must be bent by the force of gravity. The woman tries to tell him there is no such force at work; he is not an inertial observer. Nonetheless, he has the solidity of the Earth beneath him, so he insists on attributing his acceleration to the force of gravity. According to Einstein, they are both right. There is no need to distinguish locally between acceleration and gravity—the two are in some sense equivalent. But if that is the case, then it must be true that gravity—"real" gravity—can actually bend light. And indeed it can, as many experiments have shown since Einstein's first discussion of the phenomenon.

It was the genius of Einstein to go even further. Rather than speak of the force of gravitation having bent the photons into a curved path, might it not be more fruitful to think of photons as always flying in straight lines—in the sense that a straight line is the shortest distance between two points—and that what really happens is that gravitation bends space-time? In other words, perhaps gravitation is curved space-time, and photons fly along the shortest paths possible in this curved space-time, thus giving the appearance of being bent by a "force" when one insists on thinking that space-time is flat. The utility of taking this approach is that it becomes automatic that all test bodies fall at the same rate under the "force" of gravitation, for they are merely producing their natural trajectories in a background space-time that is curved in a certain fashion independent of the test bodies. What was a minor miracle for Galileo and Newton becomes the most natural thing in the world for Einstein.

To complete the program and to conform with Newton's theory of gravitation in the limit of weak curvature (weak field), the source of space-time curvature would have to be ascribed to mass (and energy). The mathematical expression of these ideas constitutes Einstein's theory of general relativity, one of the most beautiful artifacts of pure thought ever produced. The American physicist John Archibald Wheeler and his colleagues summarized Einstein's view of the universe in these terms:

Curved space-time

> Curved spacetime tells mass-energy how to move;
> mass-energy tells spacetime how to curve.

Contrast this with Newton's view of the mechanics of the heavens:

> Force tells mass how to accelerate;
> mass tells gravity how to exert force.

Notice therefore that Einstein's worldview is not merely a quantitative modification of Newton's picture (which is also possible via an equivalent route using the methods of quantum field theory) but represents a qualitative change of perspective. And modern experiments have amply justified the fruitfulness of Einstein's alternative interpretation of gravitation as geometry rather than as force. His theory would have undoubtedly delighted the Greeks.

RELATIVISTIC COSMOLOGIES

Einstein's model. To derive his 1917 cosmological model, Einstein made three assumptions that lay outside the scope of his equations. The first was to suppose that the universe is homogeneous and isotropic in the large (*i.e.*, the same everywhere on average at any instant in time), an assumption that the English astrophysicist Edward A. Milne later elevated to an entire philosophical outlook by naming it the cosmological principle. Given the success of the Copernican revolution, this outlook is a natural one. Newton himself had it implicitly in mind in his letter to Bentley (see above) when he took the initial state of the Cosmos to be everywhere the same before it developed "ye Sun and Fixt stars."

The second assumption was to suppose that this homogeneous and isotropic universe had a closed spatial geometry. As described in the previous section, the total volume of a three-dimensional space with uniform positive curvature would be finite but possess no edges or boundaries (to be consistent with the first assumption).

The third assumption made by Einstein was that the universe as a whole is static—*i.e.*, its large-scale properties do not vary with time. This assumption, made before Hubble's observational discovery of the expansion of the universe, was also natural; it was the simplest approach, as Aristotle had discovered, if one wishes to avoid a discussion of a creation event. Indeed, the philosophical attraction of the notion that the universe on average is not only homogeneous and isotropic in space but also constant in time was so appealing that a school of English cosmologists—Hermann Bondi, Fred Hoyle, and Thomas Gold—would call it the perfect cosmological principle and carry its implications in the 1950s to the ultimate refinement in the so-called steady state model.

To his great chagrin Einstein found in 1917 that with his three adopted assumptions, his equations of general relativity—as originally written down—had no meaningful solutions. To obtain a solution, Einstein realized that he had to add to his equations an extra term, which came to be called the cosmological constant. If one speaks in Newtonian terms, the cosmological constant could be interpreted as a repulsive force of unknown origin that could exactly balance the attraction of gravitation of all the matter in Einstein's closed universe and keep it from

The cosmological constant

moving. The inclusion of such a term in a more general context, however, meant that the universe in the absence of any mass-energy (*i.e.*, consisting of a vacuum) would not have a space-time structure that was flat (*i.e.*, would not have satisfied the dictates of special relativity exactly). Einstein was prepared to make such a sacrifice only very reluctantly, and, when he later learned of Hubble's discovery of the expansion of the universe and realized that he could have predicted it had he only had more faith in the original form of his equations, he regretted the introduction of the cosmological constant as the "biggest blunder" of his life. Ironically, recent theoretical developments in particle physics suggest that in the early universe there may very well have been a nonzero value to the cosmological constant and that this value may be intimately connected with precisely the nature of the vacuum state (see below).

De Sitter's model. It was also in 1917 that the Dutch astronomer Willem de Sitter recognized that he could obtain a static cosmological model differing from Einstein's simply by removing all matter. The solution remains stationary essentially because there is no matter to move about. If some test particles are reintroduced into the model, the cosmological term would propel them away from each other. Astronomers now began to wonder if this effect might not underlie the recession of the spirals.

Friedmann-Lemaître models. In 1922 Aleksandr A. Friedmann, a Russian meteorologist and mathematician, and in 1927 Georges Lemaître, the aforementioned Belgian cleric, independently discovered solutions to Einstein's equations that contained realistic amounts of matter. These evolutionary models correspond to big bang cosmologies. Friedmann and Lemaître adopted Einstein's assumption of spatial homogeneity and isotropy (the cosmological principle). They rejected, however, his assumption of time independence and considered both positively curved spaces ("closed" universes) as well as negatively curved spaces ("open" universes). The difference between the approaches of Friedmann and Lemaître is that the former set the cosmological constant equal to zero, whereas the latter retained the possibility that it might have a nonzero value. To simplify the discussion, only the Friedmann models are considered here.

Divergence from Einstein

The decision to abandon a static model meant that the Friedmann models evolve with time. As such, neighbouring pieces of matter have recessional (or contractional) phases when they separate from (or approach) one another with an apparent velocity that increases linearly with increasing distance. Friedmann's models thus anticipated Hubble's law before it had been formulated on an observational basis. It was Lemaître, however, who had the good fortune of deriving the results at the time when the recession of the galaxies was being recognized as a fundamental cosmological observation, and it was he who clarified the theoretical basis for the phenomenon.

The geometry of space in Friedmann's closed models is similar to that of Einstein's original model; however, there is a curvature to time as well as one to space. Unlike Einstein's model, where time runs eternally at each spatial point on an uninterrupted horizontal line that extends infinitely into the past and future, there is a beginning and end to time in Friedmann's version of a closed universe when material expands from or is recompressed to infinite densities. These instants are called the instants of the "big bang" and the "big squeeze," respectively. The global space-time diagram for the middle half of the expansion-compression phases can be depicted as a barrel lying on its side (Figure 6). The space axis corresponds again to any one direction in the universe, and it wraps around the barrel. Through each spatial point runs a time axis that extends along the length of the barrel on its (space-time) surface. Because the barrel is curved in both space and time, the little squares in the grid of the curved sheet of graph paper marking the space-time surface are of nonuniform size, stretching to become bigger when the barrel broadens (universe expands) and shrinking to become smaller when the barrel narrows (universe contracts).

Expansion-compression phases of the universe

It should be remembered that only the surface of the barrel has physical significance; the dimension off the surface toward the axle of the barrel represents the fourth spatial dimension, which is not part of the real three-dimensional world. The space axis circles the barrel and closes upon itself after traversing a circumference equal to $2\pi R$, where R, the radius of the universe (in the fourth dimension), is now a function of the time t. In a closed Friedmann model, R starts equal to zero at time $t = 0$ (not shown in barrel diagram), expands to a maximum value at time $t = t_m$ (the middle of the barrel), and recontracts to zero (not shown) at time $t = 2t_m$, with the value of t_m dependent on the total amount of mass that exists in the universe.

Representation of the fourth spatial dimension

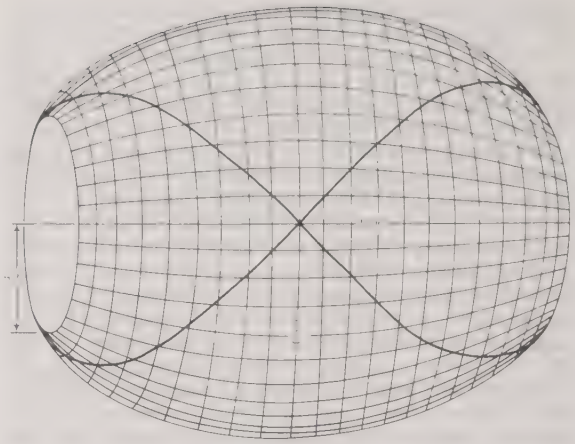

Figure 6: Curved space-time in a matter-dominated, closed universe during the middle half of its expansion-compression phases. At each instant of time t, the space axis forms a closed loop with radius $R(t)$, the so-called radius of the universe, in an unobservable fourth dimension (see text).
From F.H. Shu, *The Physical Universe* (1982); University Science Books

Imagine now that galaxies reside on equally spaced tick marks along the space axis. Each galaxy on average does not move spatially with respect to its tick mark in the spatial (ringed) direction but is carried forward horizontally by the march of time. The total number of galaxies on the spatial ring is conserved as time changes, and therefore their average spacing increases or decreases as the total circumference $2\pi R$ on the ring increases or decreases (during the expansion or contraction phases). Thus, without in a sense actually moving in the spatial direction, galaxies can be carried apart by the expansion of space itself. From this point of view, the recession of galaxies is not a "velocity" in the usual sense of the word. For example, in a closed Friedmann model, there could be galaxies that started, when R was small, very close to the Milky Way system on the opposite side of the universe. Now, 10^{10} years later, they are still on the opposite side of the universe but at a distance much greater than 10^{10} light-years away. They reached those distances without ever having had to move (relative to any local observer) at speeds faster than light—indeed, in a sense without having had to move at all. The separation rate of nearby galaxies can be thought of as a velocity without confusion in the sense of Hubble's law, if one wants, but only if the inferred velocity is much less than the speed of light.

On the other hand, if the recession of the galaxies is not viewed in terms of a velocity, then the cosmological redshift cannot be viewed as a Doppler shift. How, then, does it arise? The answer is contained in the barrel diagram when one notices that, as the universe expands, each small cell in the space-time grid also expands. Consider the propagation of electromagnetic radiation whose wavelength initially spans exactly one cell length (for simplicity of discussion), so that its head lies at a vertex and its tail at one vertex back (Figure 7). Suppose an elliptical galaxy emits such a wave at some time t_1. The head of the wave propagates from corner to corner on the little square grids that look locally flat, and the tail propagates from corner to corner one vertex back. At a later time t_2, a spiral galaxy begins to intercept the head of the wave. At time t_2, the tail is still one vertex back, and therefore the wave train, still containing one wavelength, now spans one current spatial grid spacing. In other words, the wavelength has grown in direct proportion to the linear expansion factor

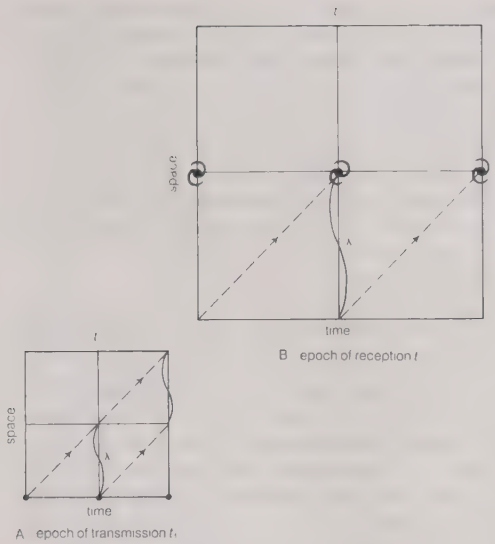

Figure 7: The cosmological redshift as a stretching of the wavelengths of photons. The cells in A and B correspond to the squares in the space-time grid of Figure 6. Each individual cell becomes larger, paralleling the linear expansion of the universe from the epoch of transmission t_1 to the epoch of reception t_2 (see text).
From F.H. Shu, *The Physical Universe* (1982), University Science Books

of the universe. Since the same conclusion would have held if n wavelengths had been involved instead of one, all electromagnetic radiation from a given object will show the same cosmological redshift if the universe (or, equivalently, the average spacing between galaxies) was smaller at the epoch of transmission than at the epoch of reception. Each wavelength will have been stretched in direct proportion to the expansion of the universe in between.

A nonzero peculiar velocity for an emitting galaxy with respect to its local cosmological frame can be taken into account by Doppler-shifting the emitted photons before applying the cosmological redshift factor; *i.e.,* the observed redshift would be a product of two factors. When the observed redshift is large, one usually assumes that the dominant contribution is of cosmological origin. When this assumption is valid, the redshift is a monotonic function of both distance and time during the expansional phase of any cosmological model. Thus, astronomers often use the redshift z as a shorthand indicator of both distance and elapsed time. Following from this, the statement "object X lies at $z = a$" means that "object X lies at a distance associated with redshift a"; the statement "event Y occurred at redshift $z = b$" means that "event Y occurred a time ago associated with redshift b."

Redshift as a monotonic function of distance and time

The open Friedmann models differ from the closed models in both spatial and temporal behaviour. In an open universe the total volume of space and the number of galaxies contained in it are infinite. The three-dimensional spatial geometry is one of uniform negative curvature in the sense that, if circles are drawn with very large lengths of string, the ratio of circumferences to lengths of string are greater than 2π. The temporal history begins again with expansion from a big bang of infinite density, but now the expansion continues indefinitely, and the average density of matter and radiation in the universe would eventually become vanishingly small. Time in such a model has a beginning but no end.

The Einstein–de Sitter universe. In 1932 Einstein and de Sitter proposed that the cosmological constant should be set equal to zero, and they derived a homogeneous and isotropic model that provides the separating case between the closed and open Friedmann models; *i.e.,* Einstein and de Sitter assumed that the spatial curvature of the universe is neither positive nor negative but rather zero. The spatial geometry of the Einstein–de Sitter universe is Euclidean (infinite total volume), but space-time is not globally flat (*i.e.,* not exactly the space-time of special relativity). Time again commences with a big bang and the galaxies recede forever, but the recession rate (Hubble's "constant") asymptotically coasts to zero as time advances to infinity.

Because the geometry of space and the gross evolutionary properties are uniquely defined in the Einstein–de Sitter model, many people with a philosophical bent have long considered it the most fitting candidate to describe the actual universe. During the late 1970s strong theoretical support for this viewpoint came from considerations of particle physics (the model of inflation to be discussed below), and mounting, but as yet undefinitive, support also seems to be gathering from astronomical observations.

Bound and unbound universes and the closure density. The different separation behaviours of galaxies at large time scales in the Friedmann closed and open models and the Einstein–de Sitter model allow a different classification scheme than one based on the global structure of space-time. The alternative way of looking at things is in terms of gravitationally bound and unbound systems: closed models where galaxies initially separate but later come back together again represent bound universes; open models where galaxies continue to separate forever represent unbound universes; the Einstein–de Sitter model where galaxies separate forever but slow to a halt at infinite time represents the critical case.

The advantage of this alternative view is that it focuses attention on local quantities where it is possible to think in the simpler terms of Newtonian physics—attractive forces, for example. In this picture it is intuitively clear that the feature that should distinguish whether or not gravity is capable of bringing a given expansion rate to a halt depends on the amount of mass (per unit volume) present. This is indeed the case; the Newtonian and relativistic formalisms give the same criterion for the critical, or closure, density (in mass equivalent of matter and radiation) that separates closed or bound universes from open or unbound ones. If Hubble's constant at the present epoch is denoted as H_0, then the closure density (corresponding to an Einstein–de Sitter model) equals $3H_0^2/8\pi G$, where G is the universal gravitational constant in both Newton's and Einstein's theories of gravity. If the numerical value of Hubble's constant H_0 is 20 km/sec per million light-years, then the closure density equals 8×10^{-30} g/cm^3, the equivalent of about five hydrogen atoms on average per cubic metre of cosmic space. If the actual cosmic average is greater than this value, the universe is bound (closed) and, though currently expanding, will end in a crush of unimaginable proportion. If it is less, the universe is unbound (open) and will expand forever. The result is intuitively plausible since the smaller the mass density, the smaller the role for gravitation, so the more the universe will approach free expansion (assuming that the cosmological constant is zero).

Criterion for closure density

The mass in galaxies observed directly, when averaged over cosmological distances, is estimated to be only a few percent of the amount required to close the universe. The amount contained in the radiation field (most of which is in the cosmic microwave background) contributes negligibly to the total at present. If this were all, the universe would be open and unbound. However, the hidden mass that has been deduced from various dynamic arguments multiplies the known amount by factors of a few to 10 or more as one considers phenomena of ever-increasing scale—from galaxies to superclusters. Thus, the total average mass density has been estimated to be 20–40 percent or more of the closure density, and many investigators would like to believe that new observations and refined estimates will eventually bring this number up to 100 percent of closure.

The age of the universe. An indirect method of inferring whether the universe is bound or unbound involves estimates of the age of the universe. The basic idea is as follows. For a given present rate of expansion (*i.e.,* Hubble's constant), it is clear that the deceleration produced by gravitation must act to make the expansion faster in the past and slower in the future. Thus, the age of the universe (in the absence of a cosmological constant) must always be less than the free expansion age, H_0^{-1}, which equals 1.5×10^{10} years. The bigger the role for gravity, the smaller the true age compared to the Hubble time H_0^{-1}. Since it can be shown that a matter-dominated Einstein–

de Sitter universe has a present age two-thirds that of the Hubble time, or 10^{10} years, the actual universe (which has been matter-dominated for a long time) is closed if it can be shown to be younger than 10^{10} years and open if older than that critical value.

As previously noted, estimates of the ages of globular cluster stars and of the ages of formation of the radioactive elements, which must be at least as old as the universe itself, give ranges of values that are roughly consistent with the critical value. The formal estimates for globular cluster ages, however, seem somewhat too large to be entirely compatible with the critical value, and some people have interpreted this to imply that either the universe is unbound or the cosmological constant is not zero. These sentiments may be premature, since the errors in the determinations are not small. Moreover, until astronomers arrive at a better understanding of the discrepancy concerning predicted and observed solar neutrino emission, it cannot be claimed that the knowledge of all physics relevant to the theory of stellar structure and evolution is completely secure.

Global observational tests. Since neither local test of average mass density nor age of the oldest accessible objects in the universe has proved decisive in showing whether the universe is bound or unbound, one might investigate large-scale diagnostics of the global structure of space-time to discriminate between closed and open universes. Conducting surveying experiments by means of space exploration of the scope described earlier is of course out of the question. Fortunately, there exist in the universe accessible natural probes with which to explore the deepest reaches of space and time—namely, photons from distant galaxies. To be able to use these probes effectively as diagnostic tools—say, in the apparent-brightness redshift or the angular-size redshift tests of classical observational cosmology—it is important to know the intrinsic properties of the emitting sources and to examine the objects with the largest possible redshifts (so one is going farthest out into space and farthest back in time). Unfortunately, these two goals yield incompatible requirements.

Photons from remote galaxies as scientific probes

The problem is that astronomers know the properties of nearby galaxies best—*i.e.,* galaxies as they appear today. The assumption that more distant (and therefore younger) galaxies look the same as they do now becomes more and more suspect as one probes deeper and deeper sources because of the increasing possibility of evolutionary effects (*e.g.,* stellar populations being younger and galaxies not yet having suffered mergers). The difficulty of disentangling the evolutionary effects from the purely cosmological ones remains the biggest obstacle to this line of research. The use of quasars or QSOs fares even worse because, though they are observable at great distances, they have a very large spread in intrinsic luminosities, and they may also suffer from evolutionary effects.

Gravitational lensing

The phenomena of gravitational lensing of quasars and galaxies into multiple images, arcs, and rings provide novel cosmological probes. For example, the light forming the different images of a lensed quasar travels different ray paths to reach the observer. Intrinsic time variability will therefore result in one image exhibiting a differential time delay with respect to another. Astronomers have exploited the fact that this differential is proportional to the overall size of the system to obtain provisional estimates for the value of the Hubble constant H_0. The probability of lensing of a quasar at high redshift, to cite another example, increases as the average mass density (mostly dark matter) in the Cosmos capable of the gravitational bending of light increases. Hence, the statistics of lensing at high redshifts could, in principle, discriminate between open and closed models of the universe. Unfortunately, the modeling of the sources is too uncertain and the detected events are too rare at present to offer decisive tests.

The ultimate fate of the universe. In the absence of definitive observational conclusions, one can only speculate on the possible fate of the actual universe. If the universe is unbound, the cosmological expansion will not halt, and eventually the galaxies and stars will all die, leaving the Cosmos a cold, dark, and virtually empty place. If the universe is bound, the mass-energy content in the distant but finite future will come together again; the cosmic background radiation will be blueshifted, raising the temperature of matter and radiation to incredible levels, perhaps to reforge everything in the fiery crucible of the big squeeze. Because of the development of structure in previous epochs, the big squeeze may not occur simultaneously everywhere at the end of time as its explosive counterpart, the big bang, seems to have done at the beginning of time. Discussions of recurring cycles of expansions and contractions thus remain highly speculative.

THE HOT BIG BANG

Given the measured radiation temperature of 2.735 K, the energy density of the cosmic microwave background can be shown to be about 1,000 times smaller than the average rest-energy density of ordinary matter in the universe. Thus, the current universe is matter-dominated. If one goes back in time to redshift z, the average number densities of particles and photons were both bigger by the same factor $(1 + z)^3$ because the universe was more compressed by this factor, and the ratio of these two numbers would have maintained its current value of about one hydrogen nucleus, or proton, for every 10^9 photons. The wavelength of each photon, however, was shorter by the factor $1 + z$ in the past than it is now; therefore, the energy density of radiation increases faster by one factor of $1 + z$ than the rest-energy density of matter. Thus, the radiation energy density becomes comparable to the energy density of ordinary matter at a redshift of about 1,000. At redshifts larger than 10,000, radiation would have dominated even over the dark matter of the universe. Between these two values radiation would have decoupled from matter when hydrogen recombined. It is not possible to use photons to observe redshifts larger than about 1,500, because the cosmic plasma at temperatures above 4,000 K is essentially opaque before recombination. One can think of the spherical surface as an inverted "photosphere" of the observable universe. This spherical surface of last scattering probably has slight ripples in it that account for the slight anisotropies observed in the cosmic microwave background today. In any case, the earliest stages of the universe's history—for example, when temperatures were 10^9 K and higher—cannot be examined by light received through any telescope. Clues must be sought by comparing the matter content with theoretical calculations.

The present universe as matter-dominated

For this purpose, fortunately, the cosmological evolution of model universes is especially simple and amenable to computation at redshifts much larger than 10,000 (or temperatures substantially above 30,000 K) because the physical properties of the dominant component, photons, then are completely known. In a radiation-dominated early universe, for example, the radiation temperature T is very precisely known as a function of the age of the universe, the time t after the big bang.

Primordial nucleosynthesis. According to the considerations outlined above, at a time t less than 10^{-4} seconds, the creation of matter-antimatter pairs would have been in thermodynamic equilibrium with the ambient radiation field at a temperature T of about 10^{12} K. Nevertheless, there was a slight excess of matter particles (*e.g.,* protons) compared to antimatter particles (*e.g.,* antiprotons) of roughly a few parts in 10^9. This is known because, as the universe aged and expanded, the radiation temperature would have dropped and each antiproton and each antineutron would have annihilated with a proton and a neutron to yield two gamma rays; and later each antielectron would have done the same with an electron to give two more gamma rays. After annihilation, however, the ratio of the number of remaining protons to photons would be conserved in the subsequent expansion to the present day. Since that ratio is known to be one part in 10^9, it is easy to work out that the original matter-antimatter asymmetry must have been a few parts per 10^9.

In any case, after proton-antiproton and neutron-antineutron annihilation but before electron-antielectron annihilation, it is possible to calculate that for every excess neutron there were about five excess protons in thermodynamic equilibrium with one another through neutrino and antineutrino interactions at a temperature of about 10^{10}

K. When the universe reached an age of a few seconds, the temperature would have dropped significantly below 10^{10} K, and electron-antielectron annihilation would have occurred, liberating the neutrinos and antineutrinos to stream freely through the universe. With no neutrino-antineutrino reactions to replenish their supply, the neutrons would have started to decay with a half-life of 10.6 minutes to protons and electrons (and antineutrinos). However, at an age of 1.5 minutes, well before neutron decay went to completion, the temperature would have dropped to 10^9 K, low enough to allow neutrons to be captured by protons to form a nucleus of heavy hydrogen, or deuterium. (Before that time, the reaction could still have taken place, but the deuterium nucleus would immediately have broken up under the prevailing high temperatures.) Once deuterium had formed, a very fast chain of reactions set in, quickly assembling most of the neutrons and deuterium nuclei with protons to yield helium nuclei. If the decay of neutrons is ignored, an original mix of 10 protons and two neutrons (one neutron for every five protons) would have assembled into one helium nucleus (two protons plus two neutrons), leaving more than eight protons (eight hydrogen nuclei). This amounts to a helium-mass fraction of $^4/_{12} = {}^1/_3$—*i.e.*, 33 percent. A more sophisticated calculation that takes into account the concurrent decay of neutrons and other complications yields a helium-mass fraction in the neighbourhood of 25 percent and a hydrogen-mass fraction of 75 percent, which are close to the deduced primordial values from astronomical observations. This agreement provides one of the primary successes of hot big bang theory.

Formation of the deuterium nucleus

The deuterium abundance. Not all of the deuterium formed by the capture of neutrons by protons would be further reacted to produce helium. A small residual can be expected to remain, the exact fraction depending sensitively on the density of ordinary matter existing in the universe when the universe was a few minutes old. The problem can be turned around: given measured values of the deuterium abundance (corrected for various effects), what density of ordinary matter needs to be present at a temperature of 10^9 K so that the nuclear reaction calculations will reproduce the measured deuterium abundance? The answer is known, and this density of ordinary matter can be expanded by simple scaling relations from a radiation temperature of 10^9 K to one of 2.735 K. This yields a predicted present density of ordinary matter and can be compared with the density inferred to exist in galaxies when averaged over large regions. The two numbers are within a factor of a few of each other. In other words, the deuterium calculation implies that a substantial fraction of all of the ordinary matter in the universe, and perhaps all of it, has already been seen in observable galaxies. Ordinary matter cannot be the hidden mass of the universe unless a large change occurs in present ideas.

THE VERY EARLY UNIVERSE

Inhomogeneous nucleosynthesis. One possible modification concerns models of so-called inhomogeneous nucleosynthesis. The idea is that in the very early universe (the first microsecond) the subnuclear particles that later made up the protons and neutrons existed in a free state as a quark-gluon plasma. As the universe expanded and cooled, this quark-gluon plasma would undergo a phase transition and become confined to protons and neutrons (three quarks each). In laboratory experiments of similar phase transitions—for example, the solidification of a liquid into a solid—involving two or more substances, the final state may contain a very uneven distribution of the constituent substances, a fact exploited by industry to purify certain materials. Some astrophysicists have proposed that a similar partial separation of neutrons and protons may have occurred in the very early universe. Local pockets where protons abounded may have few neutrons and vice versa for where neutrons abounded. Nuclear reactions may then have occurred much less efficiently per proton and neutron nucleus than accounted for by standard calculations, and the average density of matter may be correspondingly increased—perhaps even to the point where ordinary matter can close the present-day universe.

Quark-gluon plasma

Unfortunately, calculations carried out under the inhomogeneous hypothesis seem to indicate that conditions leading to the correct proportions of deuterium and helium-4 produce too much primordial lithium-7 to be compatible with measurements of the atmospheric compositions of the oldest stars.

Matter-antimatter asymmetry. A curious number that appeared in the above discussion was the few parts in 10^9 asymmetry initially between matter and antimatter (or equivalently, the ratio 10^{-9} of protons to photons in the present universe). What is the origin of such a number—so close to zero yet not exactly zero?

At one time the question posed above would have been considered beyond the ken of physics, because the net "baryon" number (for present purposes, protons and neutrons minus antiprotons and antineutrons) was thought to be a conserved quantity. Therefore, once it exists, it always exists, into the indefinite past and future. Developments in particle physics during the 1970s, however, suggested that the net baryon number may in fact undergo alteration. It is certainly very nearly maintained at the relatively low energies accessible in terrestrial experiments, but it may not be conserved at the almost arbitrarily high energies with which particles may have been endowed in the very early universe.

An analogy can be made with the chemical elements. In the 19th century most chemists believed the elements to be strictly conserved quantities; although oxygen and hydrogen atoms can be combined to form water molecules, the original oxygen and hydrogen atoms can always be recovered by chemical or physical means. However, in the 20th century with the discovery and elucidation of nuclear forces, chemists came to realize that the elements are conserved if they are subjected only to chemical forces (basically electromagnetic in origin); they can be transmuted by the introduction of nuclear forces, which enter characteristically only when much higher energies per particle are available than in chemical reactions.

Possible transmutations of the net baryon number in the very early universe

In a similar manner it turns out that at very high energies new forces of nature may enter to transmute the net baryon number. One hint that such a transmutation may be possible lies in the remarkable fact that a proton and an electron seem at first sight to be completely different entities, yet they have, as far as one can tell to very high experimental precision, exactly equal but opposite electric charges. Is this a fantastic coincidence, or does it represent a deep physical connection? A connection would obviously exist if it can be shown, for example, that a proton is capable of decaying into a positron (an antielectron) plus electrically neutral particles. Should this be possible, the proton would necessarily have the same charge as the positron, for charge is exactly conserved in all reactions. In turn, the positron would necessarily have the opposite charge of the electron, as it is its antiparticle. Indeed, in some sense the proton (a baryon) can even be said to be merely the "excited" version of an antielectron (an "antilepton").

Motivated by this line of reasoning, experimental physicists searched hard during the 1980s for evidence of proton decay. They found none and set a lower limit of 10^{32} years for the lifetime of the proton if it is unstable. This value is greater than what theoretical physicists had originally predicted on the basis of early unification schemes for the forces of nature (see below). Later versions can accommodate the data and still allow the proton to be unstable. Despite the inconclusiveness of the proton-decay experiments, some of the apparatuses were eventually put to good astronomical use. They were converted to neutrino detectors and provided valuable information on the solar neutrino problem, as well as giving the first positive recordings of neutrinos from a supernova explosion (namely, SN 1987A).

With respect to the cosmological problem of the matter-antimatter asymmetry, one theoretical approach is founded on the idea of a grand unified theory (GUT), which seeks to explain the electromagnetic, weak nuclear, and strong nuclear forces as a single grand force of nature. This approach suggests that an initial collection of very heavy particles, with zero baryon and lepton number, may decay

into many lighter particles (baryons and leptons) with the desired average for the net baryon number (and net lepton number) of a few parts per 10^9. This event is supposed to have occurred at a time when the universe was perhaps 10^{-35} second old.

Superunification and the Planck era. Why should a net baryon fraction initially of zero be more appealing aesthetically than 10^{-9}? The underlying motivation here is perhaps the most ambitious undertaking ever attempted in the history of science—the attempt to explain the creation of truly everything from literally nothing. In other words, is the creation of the entire universe from a vacuum possible?

The evidence for such an event lies in another remarkable fact. It can be estimated that the total number of protons in the observable universe is an integer 80 digits long. No one of course knows all 80 digits, but for the argument about to be presented, it suffices only to know that they exist. The total number of electrons in the observable universe is also an integer 80 digits long. In all likelihood these two integers are equal, digit by digit—if not exactly, then very nearly so. This inference comes from the fact that, as far as astronomers can tell, the total electric charge in the universe is zero (otherwise electrostatic forces would overwhelm gravitational forces). Is this another coincidence, or does it represent a deeper connection? The apparent coincidence becomes trivial if the entire universe was created from a vacuum since a vacuum has by definition zero electric charge. It is a truism that one cannot get something for nothing. The interesting question is whether one can get everything for nothing. Clearly, this is a very speculative topic for scientific investigation, and the ultimate answer depends on a sophisticated interpretation of what "nothing" means.

The words "nothing," "void," and "vacuum" usually suggest uninteresting empty space. To modern quantum physicists, however, the vacuum has turned out to be rich with complex and unexpected behaviour. They envisage it as a state of minimum energy where quantum fluctuations, consistent with the uncertainty principle of the German physicist Werner Heisenberg, can lead to the temporary formation of particle-antiparticle pairs. In flat space-time, destruction follows closely upon creation (the pairs are said to be virtual) because there is no source of energy to give the pair permanent existence. All the known forces of nature acting between a particle and antiparticle are attractive and will pull the pair together to annihilate one another. In the expanding space-time of the very early universe, however, particles and antiparticles may separate and become part of the observable world. In other words, sharply curved space-time can give rise to the creation of real pairs with positive mass-energy, a fact first demonstrated in the context of black holes by the English astrophysicist Stephen W. Hawking.

Yet Einstein's picture of gravitation is that the curvature of space-time itself is a consequence of mass-energy. Now, if curved space-time is needed to give birth to mass-energy and if mass-energy is needed to give birth to curved space-time, which came first, space-time or mass-energy? The suggestion that they both rose from something still more fundamental raises a new question: What is more fundamental than space-time and mass-energy? What can give rise to both mass-energy and space-time? No one knows the answer to this question, and perhaps some would argue that the answer is not to be sought within the boundaries of natural science.

Hawking and the American cosmologist James B. Hartle have proposed that it may be possible to avert a beginning to time by making it go imaginary (in the sense of the mathematics of complex numbers) instead of letting it suddenly appear or disappear. Beyond a certain point in their scheme, time may acquire the characteristic of another spatial dimension rather than refer to some sort of inner clock. Another proposal states that, when space and time approach small enough values (the Planck values; see below), quantum effects make it meaningless to ascribe any classical notions to their properties. The most promising approach to describe the situation comes from the theory of "superstrings."

The theory of superstrings

Superstrings represent one example of a class of attempts, generically classified as superunification theory, to explain the four known forces of nature—gravitational, electromagnetic, weak, and strong—on a single unifying basis. Common to all such schemes are the postulates that quantum principles and special relativity underlie the theoretical framework. Another common feature is supersymmetry, the notion that particles with half-integer values of the spin angular momentum (fermions) can be transformed into particles with integer spins (bosons).

The distinguishing feature of superstring theory is the postulate that elementary particles are not mere points in space but have linear extension. The characteristic linear dimension is given as a certain combination of the three most fundamental constants of nature: (1) Planck's constant h (named after the German physicist Max Planck, the founder of quantum physics), (2) the speed of light c, and (3) the universal gravitational constant G. The combination, called the Planck length $(Gh/c^3)^{1/2}$, equals roughly 10^{-33} cm, far smaller than the distances to which elementary particles can be probed in particle accelerators on the Earth.

The energies needed to smash particles to within a Planck length of each other were available to the universe at a time equal to the Planck length divided by the speed of light. This time, called the Planck time $(Gh/c^5)^{1/2}$, equals approximately 10^{-43} second. At the Planck time, the mass density of the universe is thought to approach the Planck density, c^5/hG^2, roughly 10^{93} g/cm^3. Contained within a Planck volume is a Planck mass $(hc/G)^{1/2}$, roughly 10^{-5} g. An object of such mass would be a quantum black hole, with an event horizon close to both its own Compton length (distance over which a particle is quantum mechanically "fuzzy") and the size of the cosmic horizon at the Planck time. Under such extreme conditions, space-time cannot be treated as a classical continuum and must be given a quantum interpretation.

Quantum interpretation of space-time

The latter is the goal of the superstring theory, which has as one of its features the curious notion that the four space-time dimensions (three space dimensions plus one time dimension) of the familiar world may be an illusion. Real space-time, in accordance with this picture, has 26 or 10 space-time dimensions, but all of these dimensions except the usual four are somehow compacted or curled up to a size comparable to the Planck scale. Thus has the existence of these other dimensions escaped detection. It is presumably only during the Planck era, when the usual four space-time dimensions acquire their natural Planck scales, that the existence of what is more fundamental than the usual ideas of mass-energy and space-time becomes fully revealed. Unfortunately, attempts to deduce anything more quantitative or physically illuminating from the theory have bogged down in the intractable mathematics of this difficult subject. At the present time superstring theory remains more of an enigma than a solution.

Inflation. One of the more enduring contributions of particle physics to cosmology is the prediction of inflation by the American physicist Alan Guth and others. The basic idea is that at high energies matter is better described by fields than by classical means. The contribution of a field to the energy density (and therefore the mass density) and the pressure of the vacuum state need not have been zero in the past, even if it is today. During the time of superunification (Planck era, 10^{-43} second) or grand unification (GUT era, 10^{-35} second), the lowest-energy state for this field may have corresponded to a "false vacuum," with a combination of mass density and negative pressure that results gravitationally in a large repulsive force. In the context of Einstein's theory of general relativity, the false vacuum may be thought of alternatively as contributing a cosmological constant about 10^{100} times larger than it can possibly be today. The corresponding repulsive force causes the universe to inflate exponentially, doubling its size roughly once every 10^{-43} or 10^{-35} second. After at least 85 doublings, the temperature, which started out at 10^{32} or 10^{28} K, would have dropped to very low values near absolute zero. At low temperatures the true vacuum state may have lower energy than the false vacuum state, in an analogous fashion to how solid ice

has lower energy than liquid water. The supercooling of the universe may therefore have induced a rapid phase transition from the false vacuum state to the true vacuum state, in which the cosmological constant is essentially zero. The transition would have released the energy differential (akin to the "latent heat" released by water when it freezes), which reheats the universe to high temperatures. From this temperature bath and the gravitational energy of expansion would then have emerged the particles and antiparticles of noninflationary big bang cosmologies.

Cosmic inflation serves a number of useful purposes. First, the drastic stretching during inflation flattens any initial space curvature, and so the universe after inflation will look exceedingly like an Einstein–de Sitter universe. Second, inflation so dilutes the concentration of any magnetic monopoles appearing as "topological knots" during the GUT era that their cosmological density will drop to negligibly small and acceptable values. Finally, inflation provides a mechanism for understanding the overall isotropy of the microwave background because the matter and radiation of the entire observable universe were in good thermal contact (within the cosmic event horizon) before inflation and therefore acquired the same thermodynamic characteristics. Rapid inflation carried different portions outside their individual event horizons. When inflation ended and the universe reheated and resumed normal expansion, these different portions, through the natural passage of time, reappeared on our horizon. And through the observed isotropy of the cosmic microwave background, they are inferred still to have the same temperatures. Finally, slight anisotropies in the cosmic microwave background occurred because of quantum fluctuations in the mass density. The amplitudes of these small (adiabatic) fluctuations remained independent of comoving scale during the period of inflation. Afterward they grew gravitationally by a constant factor until the recombination era. Cosmic microwave photons seen from the last scattering surface should therefore exhibit a scale-invariant spectrum of fluctuations, which is exactly what the COBE investigators claim they observed.

Mechanism for understanding the isotropy of the cosmic microwave background

As influential as inflation has been in guiding modern cosmological thought, it has not resolved all internal difficulties. The most serious concerns the problem of a "graceful exit." Unless the effective potential describing the effects of the inflationary field during the GUT era corresponds to an extremely gently rounded hill (from whose top the universe rolls slowly in the transition from the false vacuum to the true vacuum), the exit to normal expansion will generate so much turbulence and inhomogeneity (via violent collisions of "domain walls" that separate bubbles of true vacuum from regions of false vacuum) as to make inexplicable the small observed amplitudes for the anisotropy of the cosmic microwave background radiation. Arranging a tiny enough slope for the effective potential requires a degree of fine-tuning that most cosmologists find philosophically objectionable.

STEADY STATE THEORY AND OTHER ALTERNATIVE COSMOLOGIES

Big bang cosmology, augmented by the ideas of inflation, remains the theory of choice among nearly all astronomers, but, apart from the difficulties discussed above, no consensus has been reached concerning the origin in the cosmic gas of fluctuations thought to produce the observed galaxies, clusters, and superclusters. Most astronomers would interpret these shortcomings as indications of the incompleteness of the development of the theory, but it is conceivable that major modifications are needed.

An early problem encountered by big bang theorists was an apparent large discrepancy between the Hubble time and other indicators of cosmic age. This discrepancy was resolved by revision of Hubble's original estimate for H_0, which was about an order of magnitude too large owing to confusion between Population I and II variable stars and between H II regions and bright stars. However, the apparent difficulty motivated Bondi, Hoyle, and Gold to offer the alternative theory of steady state cosmology in 1948.

By that year, of course, the universe was known to be expanding; therefore, the only way to explain a constant (steady state) matter density was to postulate the continuous creation of matter to offset the attenuation caused by the cosmic expansion. This aspect was physically very unappealing to many people, who consciously or unconsciously preferred to have all creation completed in virtually one instant in the big bang. In the steady state theory the average age of matter in the universe is one-third the Hubble time, but any given galaxy could be older or younger than this mean value. Thus, the steady state theory had the virtue of making very specific predictions, and for this reason it was vulnerable to observational disproof.

Observational disproofs of the steady state theory

The first blow was delivered by Ryle's counts of extragalactic radio sources during the 1950s and '60s. These counts involved the same methods discussed above for the star counts by Kapteyn and the galaxy counts by Hubble except that radio telescopes were used. Ryle found more radio galaxies at large distances from the Earth than can be explained under the assumption of a uniform spatial distribution no matter which cosmological model was assumed, including that of steady state. This seemed to imply that radio galaxies must evolve over time in the sense that there were more powerful sources in the past (and therefore observable at large distances) than there are at present. Such a situation contradicts a basic tenet of the steady state theory, which holds that all large-scale properties of the universe, including the population of any subclass of objects like radio galaxies, must be constant in time.

The second blow came in 1965 with the discovery of the cosmic microwave background radiation. Though it has few adherents today, the steady state theory is credited as having been a useful idea for the development of modern cosmological thought as it stimulated much work in the field.

At various times, other alternative theories have also been offered as challenges to the prevailing view of the origin of the universe in a hot big bang: the cold big bang theory (to account for galaxy formation), symmetric matter-antimatter cosmology (to avoid an asymmetry between matter and antimatter), variable G cosmology (to explain why the gravitational constant is so small), tired-light cosmology (to explain redshift), and the notion of shrinking atoms in a nonexpanding universe (to avoid the singularity of the big bang). The motivation behind these suggestions is, as indicated in the parenthetical comments, to remedy some perceived problem in the standard picture. Yet, in most cases, the cure offered is worse than the disease, and none of the mentioned alternatives has gained much of a following. The hot big bang theory has ascended to primacy because, unlike its many rivals, it attempts to address not isolated individual facts but a whole panoply of cosmological issues. And, although some sought-after results remain elusive, no glaring weakness has yet been uncovered.

Ascendancy of the hot big bang theory

Summary

The history of human thought on the nature of the Cosmos offers a number of remarkable lessons, the most striking of which is that the architecture of the universe is open to reason. The plan is intricate and subtle, and each glimpse of another layer has led philosophers and scientists to a deeper mental image of the physical world. These images have surprising clarity and coherence—from the view of the Cosmos as geometry by the Greeks to the mechanistic clockwork of the Newtonian universe to the quirky subatomic "dance" of quantum particles and fields to a geometric worldview with a relativistic and quantum twist. Each generation has had members who thought that they had found the path that would penetrate to the centre of innermost truth. The present generation is no different, but is there any real reason to believe that the process has stopped with its conclusions?

Yet, incomplete though it may be, the scope of modern scientific understanding of the Cosmos is truly dazzling. It envisages that four fundamental forces, along with matter-energy and space itself, emerged in a big bang. Forged in the heat of the primeval fireball were the two simplest elements, hydrogen and helium. As the fireball expanded

and cooled, the dominance of gravity over matter led to the birth of galaxies and stars. As the stars evolved, hydrogen and helium were molded into the heavy elements, which were subsequently spewed into interstellar space by titanic explosions that occurred with the death of massive stars. The enriched debris mixed with the gas of interstellar clouds, which collected into cool dense pockets and formed new generations of stars. At the outskirts of a spiral galaxy, the gravitational collapse of a rotating molecular cloud core resulted in the formation of the Sun, surrounded by a spinning disk of gas and dust. The dust, composed of the heavy elements produced inside stars, accumulated to form planetary cores of rock and ice. One such planet was fortunate enough to have water in all three phases; and carbon chemistry in the liquid oceans of that planet gave rise to living organisms that evolved and eventually conquered the land. The most intelligent of these land animals looked up at the sky and saw the planets and the stars, and in wonderment pondered the underlying plan of the Cosmos.

BIBLIOGRAPHY

General works. Review articles on a wide variety of modern astronomy and astrophysics topics written for the scientifically literate are found in STEPHEN P. MARAN (ed.), *The Astronomy and Astrophysics Encyclopedia* (1992). Topical surveys of more limited scope are available in the *Harvard Books on Astronomy* series, especially such titles as LAWRENCE H. ALLER, *Atoms, Stars, and Nebulae*, 3rd ed. (1991); BART J. BOK and PRISCILLA F. BOK, *The Milky Way*, 5th ed. (1981); and WALLACE TUCKER and RICCARDO GIACCONI, *The X-Ray Universe* (1985). There are many introductory astronomy textbooks available that suppose little mathematical sophistication on the part of the reader; one of the most comprehensive is GEORGE O. ABELL, DAVID MORRISON, and SIDNEY C. WOLFF, *Exploration of the Universe*, 6th ed. (1991). An introduction that begins with the big bang and works forward in time is DONALD GOLDSMITH, *The Evolving Universe*, 2nd ed. (1985). At a somewhat more advanced level is FRANK H. SHU, *The Physical Universe: An Introduction to Astronomy* (1982).

History of astronomy. The standard reference is A. PANNEKOEK, *A History of Astronomy* (1961, reissued 1989; originally published in Dutch, 1951). Excellent accounts of early ideas can be found in J.L.E. DREYER, *A History of Astronomy from Thales to Kepler*, 2nd ed. (1953); and GIORGIO DE SANTILLANA, *The Origins of Scientific Thought* (1961, reissued 1970). A historical account of our understanding of galaxies and the extragalactic universe is TIMOTHY FERRIS, *Coming of Age in the Milky Way* (1988). WILLIAM SHEEHAN, *Worlds in the Sky* (1992), summarizes our current understanding of the solar system.

Planets. Useful summaries are found in BRUCE MURRAY (ed.), *The Planets* (1983), a collection of *Scientific American* articles. Also recommended is J. KELLY BEATTY and ANDREW CHAIKIN (eds.), *The New Solar System*, 3rd ed. (1990). The relationship of the origin of the solar system to theories of star formation is discussed at a technical level in DAVID C. BLACK and MILDRED SHAPLEY MATTHEWS (eds.), *Protostars and Planets II* (1985).

Stars and other cosmic components. A very readable work on stellar evolution is ROBERT JASTROW, *Red Giants and White Dwarfs*, new ed. (1990). MARTIN COHEN, *In Darkness Born: The Story of Star Formation* (1988), summarizes the processes of star formation. A classic text is MARTIN SCHWARZSCHILD, *Structure and Evolution of the Stars* (1958, reissued 1965). Stellar nucleosynthesis is the emphasis of DONALD D. CLAYTON, *Principles of Stellar Evolution and Nucleosynthesis* (1968, reprinted 1983). STAN WOOSLEY and TOM WEAVER, "The Great Supernova of 1987," *Scientific American*, 261(2):32–40 (August 1989), is a popular review. The properties of gravitationally compact stellar remnants are discussed by STUART L. SHAPIRO and SAUL A. TEUKOLSKY, *Black Holes, White Dwarfs, and Neutron Stars* (1983). HARRY L. SHIPMAN, *Black Holes, Quasars, and the Universe*, 2nd ed. (1980), is a more elementary treatment. MICHAEL W. FRIEDLANDER, *Cosmic Rays* (1989), is an introduction.

Galaxies. Beautiful photographs of galaxies together with nontechnical commentary are contained in TIMOTHY FERRIS, *Galaxies* (1980). Equally enjoyable for the amateur and professional alike are ALLAN SANDAGE, *The Hubble Atlas of Galaxies* (1961); HALTON ARP, *Atlas of Peculiar Galaxies* (1966, reprinted 1978); and ALLAN SANDAGE and G.A. TAMMANN, *A Revised Shapley-Ames Catalog of Bright Galaxies*, 2nd ed. (1987). An observational account of current ideas on the formation of our own galaxy is found in SIDNEY VAN DEN BERGH and JAMES E. HESSER, "How the Milky Way Formed," *Scientific American*, 268(1):72–78 (January 1993). Extragalactic astronomy is discussed at a level appropriate for professionals in ALLAN SANDAGE, MARY SANDAGE, and JEROME KRISTIAN (eds.), *Galaxies and the Universe* (1975, reprinted 1982); S.M. FALL and D. LYNDEN-BELL (eds.), *The Structure and Evolution of Normal Galaxies* (1981); and C. HAZARD and SIMON MITTON (eds.), *Active Galactic Nuclei* (1979). The problems of galaxy formation or galaxy clustering are described by JOSEPH SILK, *The Big Bang*, rev. and updated ed. (1989); and by P.J.E. PEEBLES, *The Large-Scale Structure of the Universe* (1980).

Cosmology. Several excellent semipopular accounts are available: TIMOTHY FERRIS, *The Red Limit: The Search for the Edge of the Universe*, 2nd rev. ed. (1983); STEVEN WEINBERG, *The First Three Minutes: A Modern View of the Origin of the Universe*, updated ed. (1988); NIGEL CALDER, *Einstein's Universe* (1979, reissued 1982); EDWARD R. HARRISON, *Cosmology, the Science of the Universe* (1981); ROBERT V. WAGONER and DONALD W. GOLDSMITH, *Cosmic Horizons* (1982); and JOHN BARROW and JOSEPH SILK, *The Left Hand of Creation: The Origin and Evolution of the Expanding Universe* (1983). MICHAEL ROWAN-ROBINSON, *The Cosmological Distance Ladder* (1985), provides a detailed discussion of how astronomers measure distances to galaxies and quasars. STEPHEN W. HAWKING, *A Brief History of Time* (1988), is a discussion by a modern scientific icon on gravitation theory, black holes, and cosmology. Standard textbooks on general relativity and cosmology include P.J.E. PEEBLES, *Physical Cosmology* (1971); STEVEN WEINBERG, *Gravitation and Cosmology* (1972); and CHARLES W. MISNER, KIP S. THORNE, and JOHN ARCHIBALD WHEELER, *Gravitation* (1973). The interface between particle physics and cosmology is the concern of G.W. GIBBONS, STEPHEN W. HAWKING, and S.T.C. SIKLOS (eds.), *The Very Early Universe* (1983). One of the best semipopular introductions to the modern attempts to unify the fundamental forces is P.C.W. DAVIES, *The Forces of Nature*, 2nd ed. (1986).

Crime and Punishment

Within a broad spectrum of cultural and historical variations, crime constitutes the intentional commission of an act usually deemed socially harmful or dangerous and specifically defined, prohibited, and punishable under the criminal law. Most countries have enacted a criminal code in which all of the criminal law can be found, although English law—the source of many other criminal law systems—remains uncodified. The definitions of particular crimes contained in a code must be interpreted in the light of many principles, some of which are not expressed in the code itself. The most important of these are related to the mental state of the accused person at the time of the act that is alleged to constitute a crime. Crimes are classified by most legal systems for purposes such as determining which court has authority to deal with the case. Social changes often result in the adoption of new criminal laws and the obsolescence of older ones.

The purpose of punishing offenders has been debated for centuries. A variety of often conflicting theories are held, and in practice each is followed to some extent. Prison is not the most common penalty for crime—a wide variety of punishments that do not involve incarceration have developed, including financial sanctions, such as fines, and schemes for service to the community in general or to the victim in particular. Juveniles are usually dealt with by courts set aside exclusively for the prosecution of young offenders.

The prison systems of most countries are subject to many problems, especially overcrowding, but the recognition by

some legal systems that prisoners have rights that the courts can enforce has led to some improvements. The death penalty is now rare in Western countries, although it has been reinstated in some parts of the United States after a period of disuse.

The present article treats the definition, incidence, and prevailing theories of criminal activity, the conduct of all stages of criminal proceedings, and various theories and practices of punishment. The material draws principally from common, or Anglo-American, law, with supplementary treatment of other systems. For full treatment of particular legal aspects of crime and punishment, see the articles CRIMINAL LAW; JUDICIAL AND ARBITRATIONAL SYSTEMS; LEGAL SYSTEMS, THE EVOLUTION OF MODERN WESTERN; POLICE; and PROCEDURAL LAW.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 521, 522, and 543.

The article is divided into the following sections:

The concept of crime

CRIMINAL CODES AND OTHER LEGAL FORMULATIONS

Criminal behaviour is defined by the laws of particular jurisdictions, and there are sometimes vast differences between and even within countries regarding what types of behaviour are prohibited. Conduct that is lawful in one country or jurisdiction may be criminal in another, and activity that amounts to a trivial infraction in one jurisdiction may constitute a serious crime elsewhere. Changing times and social attitudes may lead to changes in the criminal law, so that behaviour that was once criminal becomes lawful. Abortion, once prohibited except in the most unusual circumstances, has become lawful in many countries, as has homosexual behaviour in private between consenting adults in most Western countries, though it remains a serious offense in some parts of the world. Once criminal, suicide and attempted suicide have been removed from the scope of criminal law in many countries. Indeed, The Netherlands has decriminalized physician-assisted suicide. Nonetheless, the general trend has been toward increasing the scope of the criminal law rather than decreasing it, and it has been more common to find that statutes create new criminal offenses rather than abolish existing ones. New technologies have given rise to new opportunities for their abuse, which has led to the creation of new legal restrictions. Just as the invention of the motor vehicle led to the development of a whole body of criminal laws designed to regulate its use, so the widening use of computers and especially the Internet has created the need to legislate against a variety of new abuses and frauds—or old frauds committed in new ways.

Physician-assisted suicide

Common law. In most countries the criminal law is contained in a single statute, known as the criminal code or penal code. Although the criminal codes of most English-speaking countries are derived from English criminal law, England itself has never had a criminal code. English criminal law still consists of a collection of statutes of varying age, the oldest still in force being the Treason Act (1351), and a set of general principles that are chiefly expressed in the decisions of the courts (case law). England's lack of a criminal code is not due to a lack of effort; since the early 19th century there have been several attempts to create a code. The first effort (1833–53) was by two panels of criminal law commissioners, who systematically surveyed the prevailing state of the criminal law. A vast number of often overlapping and inconsistent statutes made determining precisely what the law provided on any particular topic enormously difficult. The existence of different statutes covering the same conduct, often with widely varying penalty provisions, permitted wide judicial discretion and inconsistency in punishments. The commissioners drew up a number of draft codes that were presented to Parliament, though none were enacted. Eventually, the judiciary's resistance led to the abandonment of the movement toward codification, and instead there was a consolidation of most of the statutory criminal law in 1861 into a number of statutes—the Larceny Act, the Malicious Damage Act, and the Offences Against the Person Act among the most important. Because these statutes were consolidations rather than codifications, they preserved many of the difficulties of the earlier legislation. The Offences Against the Person Act is still largely in force, though the others have been replaced by more modern provisions.

Interest in codification was not limited to England. A similar process ensued in India, then under British rule, and a criminal code was written during the 1830s and eventually enacted in 1860. The codes remained substantially in force in India and Pakistan and in certain parts of Africa that were once British territories. The effort to produce a criminal code in England resumed in 1877, and a further Criminal Code Bill was presented to Parliament in 1879–80. This draft code, mainly the work of the celebrated legal author and judge James Fitzjames Stephen, received widespread publicity throughout England and its colonial possessions. Although it was not adopted in England largely because Parliament was preoccupied with other matters, it was subsequently enacted in Canada in 1892 and in several Australian states and other British colonies.

Criminal law reform in the United States

Criminal law reform was one of the interests of the U.S. states in the period following the Revolution, and in the early 1820s a comprehensive draft code was prepared for Louisiana, though it was never enacted. Other states moved to codify their criminal laws. New York enacted a criminal code in 1881, setting an example that was eventually followed by most of the states. Because criminal law is primarily a matter for the individual states (in contrast

to Canada, for example, where the national parliament enacts the criminal code for the whole country), there has been considerable variation in the content of the criminal code from one state to another. In 1950 the American Law Institute began more than a decade of effort that eventually led to the publication of the Model Penal Code in 1962, an attempt to rationalize the criminal law by establishing a logical framework for defining offenses and a consistent body of general principles on such matters as criminal intent and the liability of accomplices. The Model Penal Code had a profound influence on the revision of many individual state codes over the following 20 years; although never enacted completely, the code inspired and influenced a long period of criminal code reform.

(D.A.T./Ed.)

Civil law. Whereas the legal systems of most English-speaking countries are based on English common law, those of most European and Latin American nations, as well as many countries in Africa and Asia, are based on civil law. The civil-law tradition originated in the Roman Law of the Twelve Tables (about 450 BC). In civil law the legislature, as the representative of the public, is viewed as the only valid source of law. It attempts to provide a complete, detailed, and written legal code that is understandable to the common citizen and applies in virtually all situations. Therefore, legal codes in civil-law countries tend to be much lengthier than those in common-law countries, if indeed those countries have them at all. The typical pattern in civil law includes a definition of an offense, various relevant legal principles, and a list of specific applications of the law and specific exceptions. Judges are expected to apply the law as it is written and generally are prohibited from engaging in the type of interpretation that regularly occurs in common-law systems. If more than one law applies to a case, or if the circumstances are such that the law's application is unclear, then judges refer to the legal principles that are contained in the law. Owing to the central role of the legislature in developing the legal code, civil-law systems also generally lack the type of judicial review that in some common-law countries results in what is called case law (*i.e.*, law that is derived from judicial interpretations of legislative statutes or the constitution). However, legal scholars may write treatises on specific laws and the general principles contained in those laws, and these treatises may be cited by judges in deciding particularly troubling cases, much as case law is cited in common-law countries.

Islāmic law. Countries with majority Muslim populations have adopted diverse legal systems. Those that were once English colonies (*e.g.*, Pakistan, Bangladesh, Jordan, and some of the Persian Gulf states) largely adopted English criminal law and procedure. Those under French colonial influence generally adopted civil-law systems, including the countries of the Maghrib and North Africa, including Egypt, as well as Syria and Iraq. A third group comprises those states that retained or returned to Islāmic law (called the Sharī'ah) with few or no reforms, including Iran since 1979 and Saudi Arabia.

Islāmic law is a theocratic legal system that is believed to come from God (Allāh) through the teachings of the prophet Muḥammad as recorded in the Qur'ān. The Sharī'ah serves as a criminal code that lists several *ḥadd* crimes, or offenses for which punishments are fixed and unalterable. For example, apostasy requires a death sentence, extramarital sexual relations requires death by stoning, and consuming alcoholic beverages requires 80 lashes. Other lesser crimes (*ta'zīr*) allow judges discretion in sentencing offenders.

Ḥadd crimes

Africa. Criminal offenses in most modern African countries are defined in criminal or penal codes, a radical departure from the uncodified English criminal law, on which many of these codes are based. Because of their origins, these codes reflected the penal assumptions of the original colonial power. The main concessions to local African values or problems are the inclusion of legislation against various customary practices, notably witchcraft; the extension of the criminal law in states with planned economies to cover economic crimes against the state; and, as a consequence of the soaring rate of some kinds of crime, special provision for offenses such as armed robbery. Special tribunals, not subject to the ordinary rules of procedure, have been established in many African countries to deal with such offenses.

One African country that has retained a greater role for traditional or customary law is Sierra Leone. A former British territory that obtained independence in 1961, Sierra Leone adopted a "general law" based on English common law and on the statutes of the national legislature. In 1965 these laws were consolidated in a single statute, but most of the population lived in rural areas and were governed largely by what was called "customary law." Whereas general law applies to the entire country, customary law, which originated in the customs and cultures of the indigenous peoples, varies by area or district. Customary law is enforced in separate courts in which the judges are politically appointed tribal elders. A second example is Nigeria, which established a tripartite system of criminal law and criminal justice. The criminal code is based on English common law, but there is also a penal code based on the Sharī'ah and a customary law based on the traditions of the local people.

China. For thousands of years, China tended to avoid formal law, instead basing social control on informal customary codes of behaviour, many of which were derived from the teachings of Confucius (551–479 BC). These informal codes emphasized mediation and reconciliation of conflicts, enabling all parties to "save face." They continued to be followed after the establishment of the communist People's Republic of China in 1949, in part because Chairman Mao Zedong was quite suspicious of formal law, which he regarded as a bourgeois institution. This suspicion culminated in the Cultural Revolution (1966–76), during which formal legal institutions largely disintegrated or were destroyed. The rise to power of Deng Xiaoping following the end of the Cultural Revolution brought the establishment of formal legality as part of a broad reform of Chinese society. In 1979 the National People's Congress adopted the first codes of criminal law and criminal procedure, and the first civil code was adopted in 1986. The criminal code, which was fairly simple, comprised 192 articles addressing the entire range of crimes and punishments. In practice, criminal justice officials have had considerable discretion in handling cases, and at least some criminal offenses are handled by mediation and reconciliation programs that are regulated by the state and continue the long tradition of informal and customary social control.

(Th.B./Ed.)

GENERAL PRINCIPLES OF CRIMINAL LAW

Despite differences of form and detail, there are several common general principles of criminal law throughout the English-speaking world. One widely accepted principle is the rule against retroactivity, which prohibits the imposition of *ex post facto* laws (*i.e.*, laws that would allow an individual to be punished for conduct that was not criminal at the time it was carried out). This rule restricts the authority of judges to declare new offenses (though not necessarily to expand the scope of old ones by interpretation) and has not always been accepted in England. For example, in 1960 the House of Lords, exercising its judicial power and claiming that the courts retained the authority to recognize new offenses as social needs changed, declared that it was criminal to publish a directory of prostitutes, even though no specific offense existed. In Scotland (whose legal system and criminal courts are separate from those of England) the claim is still maintained.

The rule against retroactivity

Determining what conduct constitutes a crime usually requires an examination of the terms of the relevant provisions of the code or statutory provisions (a few offenses in English law have not been defined in statute), but these have to be interpreted in the context of general principles, the most important of which is that an individual normally cannot be convicted of a crime without an intention to commit the act. In most Western countries, legal codes frequently recognize mental abnormality (*e.g.*, schizophrenia, mental retardation, or paranoia) as at least a mitigating, if not absolving, factor, though the claim of insanity has been contested.

Determining which particular conduct constitutes a crime usually requires an examination of the terms of the relevant provisions of the legal code or statutory provisions, but these must be interpreted within the context of several general principles. The most important of these principles is that criminal law as a general rule does not punish accidental or negligent behaviour. This principle, known as mens rea ("guilty mind"), is subject to many exceptions and qualifications. For some offenses (offenses of strict liability) it is abandoned completely or is allowed only a limited scope; for other offenses, notably murder, the individual must have a "specific intent" to commit the crime or to achieve the consequences of the act (the death of the victim). The fact that an individual had been drinking before committing a crime is not in itself a defense, but in some cases it is used as evidence that the accused person did not have the intention that the law requires. Provocation is not generally a defense to a criminal charge, except in the case of murder, in which evidence of a high degree of provocation (in English law, sufficient to provoke a reasonable person to act in the same way as the accused) could result in a verdict of manslaughter, even if the killing was intentional. One very rare condition that exempts individuals from criminal liability is a form of involuntary conduct known as automatism, a state (such as sleepwalking or certain effects of concussion) in which the conscious mind does not control bodily movements, thus rendering an individual unaccountable for even serious consequences.

Automatism

Criminal responsibility is not limited only to those who perform criminal acts. As a general principle, anyone who "aids and abets" a perpetrator by encouraging or in any way knowingly helping him (*e.g.,* by providing information, implements, or practical help) is an accomplice and may be considered equally guilty. Those who actually perform the criminal act (*e.g.,* wielding the weapon that strikes the fatal blow) are called principals in the first degree; those who assist at the time of the commission of the offense (*e.g.,* holding the victim down while the principal in the first degree strikes the blow) are principals in the second degree; and those who assist before the crime takes place (*e.g.,* by lending the weapon or by providing information) are accessories before the fact. Usually, all are equally responsible in the eyes of the law and liable to the same punishment. In many cases, however, the accessory before the fact is considered more culpable (*e.g.,* if he has instigated the offense and arranged for it to be committed by an associate), and in some cases the person who actually performs the act that causes the crime is completely innocent of all intent (*e.g.,* the nurse who administers to a patient, on the doctor's instructions, what he believes to be medicine but what is in fact poison). In this situation the person who carries out the act is an innocent agent and is not criminally responsible; the person who causes the innocent agent to act is the principal in the first degree. The accessory after the fact is one who helps a felon to evade arrest or conviction, possibly by either hiding him or destroying evidence. Some jurisdictions, including England, no longer use the expression, having enacted specific offenses to prosecute this type of behaviour.

Classification of crimes

GENERAL CONSIDERATIONS

Most legal systems divide crimes into categories for various purposes connected with the procedures of the courts, such as determining which kind of court may deal with which kind of offense. The common law originally divided crimes into two categories—felonies (the graver crimes, generally punishable with death and the forfeiture of the perpetrator's land and goods to the crown) and misdemeanours (for which the common law provided fines or imprisonment). The procedures of the courts differed significantly according to whether the charge was a felony or a misdemeanour; other matters that depended on the distinction included the power of the police to arrest an individual on suspicion that he had committed an offense (which was generally permissible in felony cases but not in misdemeanour ones). By the early 19th century it had become clear that the growth of the law had rendered this classification obsolete and in many cases inconsistent with the gravity of the offenses concerned (*e.g.,* theft was a felony, irrespective of the amount stolen; obtaining by fraud was always a misdemeanour). Efforts to abolish the distinction in English law did not succeed until 1967, when it was replaced by the distinction between arrestable offenses and other offenses. An arrestable offense was one punishable with five years' imprisonment or more, though offenders could be arrested for other crimes subject to certain conditions. In later legislation it proved necessary to devise further classifications. In order to provide for expanded powers of investigation, a category of serious arrestable offenses was created, and in order to determine the court in which the case should be tried, a different classification of offenses into indictable, "either way," and summary was adopted. The traditional classification between felony and misdemeanour has been retained in many American jurisdictions, though there has been a rationalization of the allocation of offenses to one category or the other, and it has been used as the basis for determining the court that will hear the case. In some jurisdictions a further class of offense, violations, was added to include minor offenses, which corresponded broadly to the English category of summary offenses.

Felony and misdemeanour

SOME PARTICULAR CRIMES

Murder. Traditionally in England murder was defined as the willful killing with malice aforethought of a human creature in being within the king's peace, the death occurring within a year and a day of the injury. Most of these elements remain in modern definitions of murder. For example, the requirement that the victim is "in being" distinguishes abortion from murder. However, in some respects the definition has become more complex. Many of the problems of defining murder have centred on the mental element—the "malice aforethought." The old English rule extended this concept to include not only intentional or deliberate killings but also accidental killings in the course of some other serious crime (such as robbery or rape). This felony murder rule was adopted in many other jurisdictions, though it often produced harsh results when death was caused accidentally in the course of what was intended to be a minor crime. The rule was abolished in England in 1957, but since then English law has been in a state of confusion over the precise definition of murder. It generally has been determined that an intention to kill is not necessary and that an intention to cause serious bodily injury is, though the precise interpretation of intention has remained controversial. Similar problems have arisen in the United States, where some jurisdictions have distinguished between different degrees of murder. Murders that include both premeditation (*i.e.,* thinking about the act beforehand and deciding to do it) and specific intent (*i.e.,* intending not only the act itself but also the death of the victim) have always been classified as first degree. In most states felony murders are also considered first degree even though they may involve neither premeditation nor intent. In most cases, however, homicide without the intent to kill is considered manslaughter. Virtually all systems treat murder as a crime of the utmost gravity, and some provide for the death penalty or mandatory life imprisonment (often with restrictions on parole) in certain cases. A high proportion of murders are committed spontaneously by persons acquainted with the deceased—often a member of the same family—and convicted murderers are often people with no other criminal conviction.

Malice aforethought

Rape. The traditional legal definition of rape is the performance of sexual intercourse against a woman contrary to her will by a man other than her husband by force or fraud. This definition has been revised in the statutes of some jurisdictions; in Canada, for example, the crime of rape has been abolished as a separate offense and merged into a wider general category of sexual assault. Historically, most jurisdictions did not treat an act of sexual intercourse by a husband with his wife without her consent as rape, unless the marriage had been effectively terminated by a legally recognized separation. However, many jurisdictions have passed "marital rape" laws, which made it illegal for husbands to force their wives to have sex. By the 1990s every U.S. state and Washington, D.C., had passed

marital rape laws. Although many rapes involve the application or threat of violence, it is possible to commit rape by fraud, either by persuading the victim that what is to take place is not sexual intercourse (*e.g.*, by representing it as medical treatment) or by impersonating some other person, such as the victim's husband. Under most criminal codes, rape requires penetration of the female organ by the male organ (but does not require ejaculation); other forms of sexual abuse (such as oral penetration or anal penetration) are dealt with, if at all, under different provisions. In the United States, the crime of rape may also include forcible sodomy, and victims of rape may be women or men. The main issue in many rape trials is whether the complainant consented to the sexual intercourse, and this has often led to distressing cross-examination about the victim's previous sexual behaviour. In response, many jurisdictions adopted "rape shield laws," which restrict such cross-examination and often forbid publication of the complainant's identity. Opponents of these laws have argued that they hamper the ability of defendants to receive a fair trial. Guilt in some rape trials often has been difficult to establish because of the need to prove not only that the victim did not consent but also that the accused knew this or at least was aware of that possibility.

"Rape shield laws"

Most criminal systems treat rape as a grave crime. For example, 95 percent of those convicted of rape in England are sentenced to imprisonment. However, many rapists escape arrest and conviction for a variety of reasons. Victims often are reluctant to report rapes because of a fear of embarrassment or of hostile treatment by investigating authorities or by defense lawyers. Further, because there are rarely any witnesses other than the complainant, defendants often are acquitted, though convictions have increased somewhat with the use of DNA testing. The motivation of rapists is acknowledged to be more complex than was formerly believed; it is widely accepted that rape is not necessarily the result of sexual desire but is more likely to be motivated by aggression and the desire to humiliate or exercise domination over the victim.

Perjury. Perjury originally consisted of the giving of false evidence on oath to a court of law, but it has been expanded to include evidence given under affirmation to other tribunals that have the authority of the law. Perjury may be committed by witnesses from either the prosecution or the defense (or by witnesses on either side in civil litigation) and in proceedings before the jury or after the verdict in proceedings leading to sentence. To be guilty of perjury, an accused person must make a false statement and must either know the statement to be false or not believe it to be true, and the false statement must normally be material to the matters at issue in the proceedings. In many jurisdictions the law imposes special requirements for the proof of perjury—it is not normally sufficient to rely on the evidence of one witness of the alleged perjured statement. Crimes associated with perjury include subornation of perjury (*i.e.*, persuading other persons to commit perjury) and a wide variety of statutory offenses involving making false statements in official documents (such as applications for drivers' licenses).

Subornation of perjury

Prostitution. Laws regulating prostitution vary greatly. In some jurisdictions prostitution—generally defined as the provision of sexual services for money—is illegal; in others the act of prostitution is not illegal in itself, but many associated activities are unlawful. For example, in colonial America prostitution was not illegal, but a woman could be arrested for vagrancy if she was loitering on the streets. English law does not prohibit prostitution but does prohibit soliciting for prostitution in a public place, living on the earnings of prostitution, exercising control over prostitutes, or maintaining a brothel (defined as any premises where two or more prostitutes are employed). In some jurisdictions, notably in most counties in the U.S. state of Nevada, prostitution is lawful and practiced openly subject only to health and related controls. In The Netherlands, prostitution is legal, and many prostitutes have become members of a professional service union.

Theft, burglary, and robbery. Theft, sometimes still known by the traditional name of larceny, is probably the most common crime involving criminal intent. The crime of grand larceny in some U.S. jurisdictions consists of stealing more than a specified sum of money or property worth more than a specified amount. Theft was traditionally defined as the physical removal of an object that is capable of being stolen without the consent of the owner and with the intention of depriving the owner of it permanently. This intention, which has always been an essential feature of theft, does not necessarily mean that the thief must intend to keep the property—an intention to destroy it, or to abandon it in circumstances where it will not be found, is sufficient. For example, the "unauthorized use" of an automobile, which typically involves taking the car for a "joy ride" and then abandoning it in such a way that the owner is unable to reclaim it, is considered a form of theft. In many legal systems the traditional definition has been deemed inadequate to deal with modern forms of property that may not be physical or tangible (*e.g.*, a bank balance or data stored on a computer), and more sophisticated definitions of theft have been adopted in modern legislation. The distinction that common-law systems made between theft (taking without consent) and fraud (obtaining with consent through deception) has been preserved in many jurisdictions. However, the two crimes are now rarely regarded as mutually exclusive, and it is generally accepted that an act may constitute both theft and fraud, such as the theft and subsequent sale of an automobile.

Fraud

Burglary originally consisted of breaking into a dwelling at night with the intention of committing a felony, but the definition has been expanded in many legal systems. In English law, any entry by an individual into a building as a trespasser with the intention of committing theft or certain other offenses is burglary, and some jurisdictions recognize an offense of burglary of an automobile (*e.g.*, breaking into it in order to steal the contents). The essence of burglary is normally the entry into a building with the intention of committing a crime of the kind specified in the burglary statute; entry without such an intention is trespassing, which is not criminal in many jurisdictions. Although the motivation of most burglars is theft, the intention to commit various other offenses converts a trespass into a burglary. For example, it is possible to commit burglary with the intention to rape.

Robbery is the commission of theft in circumstances of violence and involves the application or the threat of force in order to commit the theft or to secure escape. Robbery takes many forms, from the mugging of a stranger in the street in the hope of stealing whatever he may happen to have in his possession, to much more sophisticated robberies of banks or similar premises, involving numerous participants and careful planning. (D.A.T./Th.B./Ed.)

OTHER MODES OF CRIMINAL ACTIVITY

Organized crime. In addition to individual criminals acting independently or in small groups, there are criminal organizations engaged in offenses such as cargo theft, fraud, robbery, kidnapping for ransom, and the demanding of "protection" payments. The principal source of income for these organizations is the supply of goods and services that are illegal but for which there is continued public demand, such as drugs, prostitution, "loan-sharking" (*i.e.*, lending money at extremely high rates of interest), and gambling.

Criminal organizations in the United States are best viewed as shifting coalitions, normally local or regional in scope. In Australia extensive narcotics, cargo theft, and labour racketeering rings have been discovered; in Japan there are gangs specializing in vice and extortion; in Asia organized groups, such as the Chinese Triads, engage in drug trafficking; and in Britain there are syndicates engaging in cargo theft at airports, vice, protection, and pornography. There also are many relatively short-term groups drawn together for specific projects, such as fraud and armed robbery, from a pool of long-term professional criminals.

Apart from the drug trade, the principal form of organized crime in many developing countries is the black market, which involves such criminal acts as smuggling and corruption in the granting of licenses to import goods and to export foreign exchange. Armed robbery has been par-

ticularly popular and easy because of the widespread availability of arms supplied to nationalist movements by those seeking political destabilization of their own or other countries. After the dissolution of the Soviet Union, organized-crime rings flourished in Russia. By the beginning of the 21st century, official Russian crime statistics had identified over 5,000 organized-crime groups responsible for international money laundering, tax evasion, and assassinations of businessmen and politicians. One report even argued that Russia was on the "verge of becoming a criminal syndicalist state, dominated by a lethal mix of gangsters, corrupt officials, and dubious businessmen."

White-collar crime. Crimes committed by business people, professionals, and politicians in the course of their occupation are known as white-collar crimes, after the typical attire of their perpetrators. Contrary to popular usage, criminologists tend to restrict the term to those illegal actions intended by the perpetrators principally to further the aims of their organizations rather than to make money for themselves. Examples include conspiring with other corporations to fix the prices of goods or services in order to make artificially high profits or to drive a particular competitor out of the market; bribing officials or falsifying reports of tests on pharmaceutical products to obtain manufacturing licenses; and constructing buildings or roads with cheap, defective materials while charging for components meeting full specifications. Sometimes such activities can be attributed to individual overenthusiastic employees or to executives acting on their own initiative, but other times they represent a collective and organized effort within a corporation to increase profit at any cost. White-collar crime that is part of a collective and organized effort to serve the economic interests of a corporation is known as corporate crime.

Corporate crime

The cost of corporate crime is many times that of organized crime or the more common "street" crime. Corporate crimes have a huge impact on the safety of workers, consumers, and the environment, but they are seldom detected. Compared with crimes committed by juveniles or the poor, corporate crimes are very rarely prosecuted in the criminal courts and executives seldom go to jail, though some companies may pay large fines.

Besides corporate crime, the public and academics often use the term white-collar crime to describe fraud and embezzlement. Rather than being crimes "by the firm, for the firm," these acts constitute crime for profit by an individual against the organization, the public, or the government (*e.g.,* tax fraud costs more than 5 percent of the gross national product in many developed countries). Owing to the concealed nature of many frauds and the fact that few are reported even when discovered, their cost is impossible to estimate precisely, but in the United States it is thought to be at least 10 times the combined cost of theft, burglary, and robbery. (Mi.L./Ed.)

Terrorism. Beginning in the 1960s international terrorist crimes, such as the hijacking of passenger aircraft, political assassinations and kidnappings, and urban bombings, have been a major concern—especially to Western governments, which are the frequent targets of such acts. Most terrorist groups are associated either with millenarian revolutionary movements on an international scale or with nationalist movements of a particular ethnic, religious, or other cultural focus.

Three broad categories of terrorist crime can be distinguished, not in legal terms but by intention. Foremost is the use of violence and the threat of violence to create public fear, which may take the form of random attacks to injure or kill anyone who happens to be in the vicinity when an attack takes place. Because such crimes deny, by virtue of their being directed at innocent bystanders, the unique worth of the individual, terrorism has often been recognized as a crime that runs counter to all morality and undermines the foundations of civilization. Another tactic that generates fear is the abduction and assassination of heads of state and members of governments in order to make others afraid of taking positions of leadership and to spread a sense of insecurity. Persons in responsible positions may be abducted or assassinated on the grounds that they are "representatives" of some institution or system to which their assailants are opposed, as in the case of the 1991 assassination of Rajiv Gandhi, India's former prime minister, by Tamil separatists from Sri Lanka.

A second category of terrorist crime is the use of terror by a terrorist organization against its own members or against the community it claims to serve in order to enforce obedience and to ensure loyalty and support. A related form of terrorism, known as state, or state-sponsored, terrorism, is the use of terror by a country (or an agent of a government) against its own citizens or against civilian citizens of another country.

Third, crimes are sometimes committed by terrorist organizations in order to gain the means for their own support. Bank robbery, kidnapping for ransom, extortion, illegal arms dealing, and drug trafficking are among the principal crimes of this nature. (Ji.B./Ed.)

Measurement of crime

Estimating the amount of crime actually committed has long troubled criminologists. Figures for recorded crime do not generally provide an accurate picture because they are influenced by variable factors, such as the willingness of victims to report crimes. It is widely believed that only a small fraction of crimes are reported to authorities. Thus, criminals detected are not necessarily representative of all those who commit crime, making attempts to explain the causes of crime difficult.

The public's view of the frequency and seriousness of crime is derived largely from the news and entertainment media, and, because the media usually focus on serious or sensational crimes, the public's view is often seriously distorted. A more detached view is generally provided by detailed statistics of crime compiled and published by government departments. For example, the United States Federal Bureau of Investigation (FBI) annually publishes the *Uniform Crime Reports,* and in Great Britain the Home Office produces an annual volume entitled *Criminal Statistics, England and Wales.* Official statistics frequently are used by policy makers as the basis for new crime-control measures (*e.g.,* they may show an increase in the incidence of a particular type of crime over a period of years and suggest that some change in the methods of dealing with that type of crime is necessary). However, official crime statistics are subject to error and may be misleading, particularly if they are used without an understanding of the processes by which they are compiled and the limitations to which they are necessarily subject. The statistics are usually compiled on the basis of reports from police forces and other law enforcement agencies and are generally known as statistics of reported crime, or crimes known to the police. Because only incidents observed by the police or reported to them by victims or witnesses are included in the reports, the picture of the amount of crime actually committed may be distorted. One factor accounting for this distortion is the extent to which police resources are allocated to the investigation of one kind of crime rather than another, particularly with regard to what are known as "victimless crimes," such as the possession of drugs. These crimes are not discovered unless the police endeavour to look for them, and they do not figure in the statistics of reported crime unless the police take the initiative. Thus, a sudden increase in the reported incidence of a crime from one year to the next may merely show that the police have taken more interest in that crime and have devoted more resources to its investigation. Ironically, efforts to discourage or eliminate a particular kind of crime through more vigorous law enforcement may create the impression that the crime concerned has increased, because more instances are detected and thus enter the statistics.

Crime statistics

A second factor that can have a striking effect on the apparent statistical incidence of a particular kind of crime is a change in the willingness of victims of the crime to report it to the police. Victims may not report crimes for a variety of reasons: they may fail to realize that a crime has been committed against them (*e.g.,* children who have been sexually molested); they may believe that the police will not be able to apprehend the offender; they may fear

serving as a witness; or they may be embarrassed by the conduct that led them to become the victim of the crime (*e.g.*, a man robbed by a prostitute or a person who becomes the victim of a confidence trick as a result of his own greed or credulity). Some crimes also may not appear sufficiently serious to make it worthwhile to inform the police, or there may be ways in which the matter can be resolved without involving them (*e.g.*, an act of violence by one schoolchild against another may be dealt with by the school authorities). All these factors are difficult to measure with any degree of accuracy, and there is no reason to suppose that they remain constant over time. Thus, a change in any one of these factors may produce the appearance of an increase or a decrease in a particular kind of crime when there has been no such change or the real change has been on a much smaller scale than the statistics suggest.

A third factor that may affect the picture of crime presented by official statistics is the way in which the police treat particular incidents. Many of the laws defining crimes are imprecise or ambiguous, such as those regarding reckless driving, obscenity, and gross negligence. Some conduct that is treated as criminal in one police jurisdiction may not be treated similarly in another jurisdiction owing to differences in priorities or interpretations of the law. Another practice that influences crime statistics is the recording process; the theft of a number of items may be recorded as a single theft or as a series of thefts of the individual items.

Criminologists have endeavoured to obtain a more accurate picture of the incidence of crimes and the trends and variations from one period and jurisdiction to another. One research method that has been particularly useful is the victim survey, in which the researcher identifies a representative sample of the population and asks individuals to disclose any crime of which they have been victims during the period specified in the research. After a large number of people have been questioned, the information obtained from the survey is then compared with the statistics for reported crime for the same period and locality, giving an indication of the relationship between the actual incidence of the type of crime in question and the number of cases reported to the police. Although criminologists have developed sophisticated procedures for interviewing victim populations, such projects are subject to a number of limitations. Results depend entirely on the recollection of incidents by victims, their ability to recognize that a crime has been committed, and their willingness to disclose it. This method is inapplicable to victimless crimes.

Victimization surveys

The United States Bureau of the Census began conducting an annual survey of crime victims in 1972. By the late 1990s the survey included a random sample of about 45,000 households in which approximately 95,000 residents age 12 and over were interviewed twice a year and asked whether they had been the victims of any of a wide variety of offenses in the past six months. The results of the survey found that total violent crimes had remained relatively stable until 1992, when rapes, robberies, and aggravated assaults declined and simple assaults increased. In the mid-1990s the number of simple assaults began to decline, and by the end of the 20th century total violent crime had declined by nearly one-third from its 1993 level. Property crime declined continuously from 1975 to the late 1990s, with the decline accelerating in the early 1990s. By 1995 crime was at about half the 1973 level, and the overall property crime rate fell another one-fifth during the next two years. By the late 1990s the rates of violent crime and property crime were at their lowest recorded levels. In contrast, the FBI's *Uniform Crime Reports* showed crime rising steeply throughout the 1970s and '80s and peaking in 1994. By 1998 the total number of serious violent and property crimes had declined by approximately 15 percent from its 1994 high. Comparing these two data sources, it can be estimated that about half of all violent victimizations and about one-third of all property victimizations were reported to the police. The most common explanation for the differences in the trends reported is that the victim survey data reflect the actual trends in the incidence of criminal behaviour, and the data in the *Uniform Crime Reports* primarily reflect increases in the reporting of crimes to the police by victims. Many other countries have adopted victim surveys, including Britain, France, Germany, Sweden, Canada, Israel, and New Zealand. The United Nations (UN) sponsors an international crime victim survey.

An alternative approach favoured by some criminologists is the self-report study, in which a representative sample of individuals is asked, under assurances of confidentiality, whether they have committed any offenses of a particular kind. This type of research is subject to some of the same difficulties as the victim survey—the researcher has no means of verifying the information and the subjects can easily conceal the fact that they have committed an offense at some time—but these surveys have often confirmed that large numbers of offenses have been committed without being reported and that crime is much more widespread than official statistics suggest.

Analysis of crime

CHARACTERISTICS OF OFFENDERS

Knowledge of the types of people who commit crimes is subject to one overriding limitation: it is generally based on studies of those who have been arrested, prosecuted, and convicted. These populations are not necessarily typical of the whole range of criminals, representing only unsuccessful criminals. Despite this limitation, some basic facts emerge that give a reasonably accurate picture of those who commit crimes. For example, crime is predominantly a male activity. In all criminal populations, whether of offenders passing through the courts or of those sentenced to institutions, men outnumber women by a high proportion, especially in more serious offenses. For example, at the end of the 1990s in the United States men accounted for approximately 80 percent of all arrests, 85 percent of arrests for violent offenses, and 90 percent of arrests for homicide. At the beginning of the 21st century in Britain, the daily average population of the prisons consisted of approximately 60,000 men and 3,000 women. Nevertheless, in most Western societies the incidence of recorded crime by women and the number of women in the criminal justice systems has increased. For example, from 1994 to 1998 overall arrests of males in the United States rose slightly and arrests for violent offenses declined by more than one-tenth; conversely, overall arrests of females and arrests of women for violent offenses increased by more than one-tenth. These figures indicated a trend of increasing criminal activity by women and suggested to some observers that the changing social role of women had led to greater opportunity and temptation to commit crime. However, an alternative explanation is that the change in the apparent rate of female criminality merely reflected a change in the operation of the criminal justice system, which routinely had ignored crimes committed by women. Although arrest data suggested that female criminality had increased faster than male criminality, the national crime victim survey showed that violent offending in the United States by both males and females had fallen in the same years. In addition, the female murder rate in 1998 was at its lowest level since 1976 and about two-fifths below its peak level in 1980. (Th.B./Ed.)

Predominance of male criminals

A second aspect of criminality about which there is a reasonable measure of agreement is that crime is predominantly an activity of the young. In both Britain and the United States, for example, the peak period for involvement in relatively minor property crime is adolescence—from 15 to 21. For involvement in more serious crimes the peak age is likely to be rather higher, from the late teenage years through the 20s. Criminality tends to decline steadily after the age of 30. Criminologists have sought explanations of this phenomenon—whether it is a natural effect of aging, the consequence of taking on family responsibilities, or the effect of experiencing penal measures imposed by the law for successive convictions—but the evidence is inconclusive. Not all types of crime are subject to decline with aging. Fraud and certain kinds of theft, as well as crimes requiring a high level of businesslike organization, are more likely to be committed by older men,

The youth factor

and sudden crimes of violence, committed for emotional reasons, may occur at any age.

Social and economic status

The relationship between social class or economic status and crime has been studied extensively by criminologists. Studies carried out in the United States in the 1920s and '30s claimed to show that a higher incidence of criminality was concentrated in deprived and deteriorating neighbourhoods of large cities, and studies of penal populations revealed that the level of educational and occupational attainments was generally lower than in the wider population. Early studies of juvenile delinquents dealt with by courts disclosed a high proportion of lower-class offenders. Later research has called into question the assumption that criminality is closely associated with social origin; in particular, self-report studies have suggested that offenses are more widespread across the social spectrum than the figures based on identified criminals would suggest.

The relationship between racial or ethnic origin and criminality is a difficult and controversial question. Penal populations probably contain a disproportionately high number of persons from some minority racial groups, in the sense that the proportion of minority group members in prison is greater than the group's proportion in the general population. Criminologists have pointed out that this may be the result of the high incidence among minority racial groups of characteristics that are commonly associated with identified criminality—*e.g.*, unemployment and low economic status—and the fact that in many cities racial minority groups inhabit areas that have traditionally been high crime areas, perhaps as a result of their shifting populations and general lack of social cohesion. Further explanations are differential enforcement practices on the part of the police and the adherence of members of some minority groups to cultural standards that are in conflict with the general law (*e.g.*, the widespread use of cannabis [marijuana] by members of the predominantly black Rastafarian sect).

THEORIES OF CAUSATION

Few modern criminologists would claim that any single theory constitutes a universal explanation of criminality or a valid predictor of future criminal behaviour in a particular population. A more common view is that many of the different theories offered may help to explain particular aspects of criminality and that different types of explanation may all contribute to the understanding of the problem of crime.

Biological theories. Some theories attribute the tendency toward criminality to innate biological factors. The most famous of these is probably that of the Italian

Lombroso's theory

Cesare Lombroso (1835–1909), one of the first scientific criminologists, whose theories were related to Darwinian theories of evolution. His investigations of the skulls and facial features of robbers led him to the hypothesis that serious or persistent criminality was associated with atavism, or the reversion to a primitive stage of human development. Another biological theory related criminality to body types, suggesting that it was more common among muscular, athletic persons (mesomorphs) than among tall, thin persons (ectomorphs) or soft, rounded individuals (endomorphs). These theories have little support today, but there is some interest in the idea that criminality may be related to chromosomal abnormalities—in particular, the idea that so-called XYY males (characterized by the presence of a surplus Y chromosome) may be more likely to be involved in criminal behaviour than the general population.

Twin studies

Some criminologists have endeavoured to answer the question of whether biological factors are more important than social factors in criminal behaviour by studying the behaviour of twins. Various studies have shown that twins are more likely to exhibit similar tendencies toward criminality if they are identical (monozygotic) than if they are fraternal (dizygotic). The suggestion of genetic influences in criminal behaviour is supported by studies of adopted children carried out to determine the influence of the biological parent on criminality. One such study showed that the rate of criminality was higher among those adopted children who had one biological parent who was criminal than among those who had one adoptive parent who was criminal but whose biological parents were not. The highest rates of criminality were found among those children who had both biological parents and adoptive parents who were criminal.

Sociological theories. Sociologists have proposed a variety of theories that explain criminal behaviour as a normal adaptation to the offender's social environment. One such theory, known as differential association, proposed that all criminal behaviour is learned behaviour and that the process of learning criminal behaviour depends on the extent of the individual's contact with other persons whose behaviour reflects varying standards of legality and morality. The more the individual is exposed to contact with persons whose own behaviour is unlawful, the more likely he is to learn and adopt their values as the basis for his own behaviour. The theory of anomie, proposed by the American Robert K. Merton, suggested that criminality is a result of the offender's inability to attain by socially acceptable means the goals that society expects of him; faced with this inability, the individual is likely to turn to other, not necessarily socially acceptable, objectives or to pursue the original objectives by unacceptable means. A development from this theory is the concept of the subculture—an alternative set of moral values and conventional expectations to which the person can turn if he cannot find acceptable routes to the objectives held out for him by the broader society. This theory, developed particularly with reference to delinquent gangs in U.S. cities, has been disputed by other sociologists who deny the existence of any subculture of delinquency among the lower classes of society; the behaviour of gangs is for these latter sociologists an expression of widespread lower-class values emphasizing toughness and excitement.

Theory of anomie

A further group of sociological theories denies the existence of subcultural value systems and portrays the delinquent as an individual who subscribes generally to the morals of society but who is able to justify to himself particular forms of delinquent behaviour by a process of "neutralization," in which the behaviour is redefined in moral terms to make it acceptable. Control theory emphasizes the links between the offender and his social group—the individual's bond to society. According to this theory, the ability of the individual to resist the inclination to commit crime—which may be an easy way to satisfy a particular desire—depends on the strength of his attachment to parents, his involvement with conventional activities and avenues of progress, and his commitment to orthodox moral values that prohibit the conduct in question. Labeling theory, by contrast, portrays criminality as a product of the reaction of society to the individual, rather than of his own inclinations and personality. It assumes that the criminal is not substantially different from any other individual, except that he has become involved in the processes of the criminal justice system and has acquired a "criminal" identity. Through a process of rejection by law-abiding persons and acceptance by other delinquents, which is a consequence of the criminal identity conferred on him by the courts, the offender becomes more and more socialized into criminal behaviour patterns and estranged from law-abiding behaviour. Eventually he comes to see himself cast by society into the role of a criminal, and he acts out society's expectations. Each time he passes through the court system, the process is extended to form a process described as "amplification of deviance." Radical criminologists change the focus of inquiry, looking for the causes of delinquency not in the individual but in the structure of society, in particular its political and legal systems. The criminal law is seen as an instrument by which the powerful and affluent maintain their position and coerce the poor into patterns of behaviour that preserve the status quo.

Psychological theories. Psychologists have approached the task of explaining delinquent behaviour by examining in particular the processes by which behaviour and restraints on behaviour are learned. Psychoanalytical theories emphasize the instinctual drives for gratification and the control exercised through the more rational aspect of personality, the superego. Criminality is seen to result from

Behavioral theory of crime

the failure of the superego, as a consequence either of its incomplete development or of unusually strong instinctual drives. The empirical basis for such a theory is necessarily thin. Behaviour theory views all behaviour—criminal and otherwise—as learned and thus manipulable by the use of reinforcement and punishment. Social learning theory examines the manner in which behaviour is learned from contacts within the family and other intimate groups, from social contacts outside the family, particularly from peer groups, and from exposure to models of behaviour in the media, particularly television.

Mental illness is the cause of a relatively small proportion of crimes, but its importance as a causative factor may be exaggerated by the seriousness of some of the crimes committed by persons with mental disorders. Severe depression or psychopathy (sometimes described as sociopathy or personality disorder) may lead to grave offenses of violence. On a less serious level, depression may lead to theft or other uncharacteristic behaviour. (D.A.T.)

A non-Western perspective: China. The Chinese have in general adopted a Marxist interpretation of the causes of crime. Crime is viewed as a product of class society, of exploitative systems founded upon the institution of private property. Because the socialist system is considered by its proponents as incapable of producing crime, official theory has always looked outside of post-1949 Chinese society to find the causes of contemporary crime. A number of specific sources of criminal activity have been suggested: (1) external enemies and remnants of the overthrown reactionary classes (the latter referring to the government of the Republic of China in Taiwan) who infiltrate the country with spies and conduct sabotage; (2) remains of the old (pre-1949) society, such as gangsters and hooligans, who refuse to reform; (3) lingering aspects of bourgeois ideology that prize profit, cunning, selfishness, and decadence and thus encourage crime; and (4) the poverty and cultural backwardness that is seen as the legacy of the old society. The Cultural Revolution (1966–76) has also been cited as a cause of crime; it is said to have confused notions of right and wrong and to have destroyed respect for authority.

While Chinese criminology thus adopts a social explanation of crime in capitalist society, it has little sympathy for the view that society is to blame for crime in contemporary China. The two main causes are seen to be backward thinking and ignorance. For this reason, crime is ideally to be fought, and ultimately eliminated, by thought reform and by education. (D.C.C.)

Detection of crime

In most countries the detection of crime is the responsibility of the police, although special law enforcement agencies may be responsible for the discovery of particular types of crime (customs departments, for instance, may be responsible for the detection of smuggling and related offenses). Crime detection falls into three distinguishable phases: the discovery that a crime has been committed, the identification of a suspect, and the collection of sufficient evidence to indict the suspect before the court. Criminologists have shown that a high proportion of crimes are discovered and reported by persons other than the police (such as victims or witnesses), but certain types—in particular crimes that may involve a subject's assent, such as dealing in drugs or prostitution, or those in which there may be no identifiable victim, such as obscenity—are often not discovered unless the police take active steps to determine whether these crimes are being committed. This may require controversial methods, such as surveillance, interception of communications, infiltration of gangs, and entrapment (*e.g.*, by making a purchase from a suspected drug dealer). Once the commission of a crime has been discovered, the identification of the suspect becomes essential.

THE ROLE OF FORENSIC SCIENCE

Fingerprinting

Forensic science has come to play an increasingly important part in the investigation of serious crimes. One of the first significant developments was identification by fingerprints. It was discovered in the 19th century that almost any contact between a finger and a fixed surface left a latent mark that could be exposed by a variety of procedures, the most common being the use of a fine powder. It was accepted in 1893, by the Troup Committee established by the Home Secretary, that no two individuals had the same fingerprints, and this proposition has never been seriously refuted. Fingerprint evidence was accepted for the first time in an English court in 1902. The original purpose of recording and collecting fingerprints was to establish and to make readily available the criminal record of particular offenders, but fingerprinting is now widely used as a means of identifying the perpetrators of particular offenses. Most major police forces maintain collections of fingerprints taken from known criminals at the time of their conviction, for use in identifying these individuals should they commit later crimes. Fingerprints (which may be incomplete) found at the scene of the crime are matched with fingerprints in the collection. According to the British standard, if the sets of fingerprints share at least 16 characteristics, it is considered virtually certain that they are from the same person. Searching fingerprint collections had historically been a time-consuming manual task, based on various systems of classification, but systems for electronic storage and rapid searching of fingerprint collections were developed and implemented in the 1980s.

A broad range of other scientific techniques is available to law enforcement agencies attempting to identify suspects or to establish beyond doubt the connection between a suspect and the crime in question. Examples include the analysis of bloodstains and traces of other body fluids (such as semen or spittle) that may indicate some of the characteristics of the offender. Fibres can be analyzed by microscopy or chemical analysis to show, for instance, that fibres found on the victim or at the scene of the crime are similar to those in the clothing of the suspect. Hair samples, and particularly skin cells attached to hair roots, can be compared chemically and genetically to those of the suspect. Many inorganic substances, such as glass, paper, and paint, can yield considerable information under microscopic or chemical analysis. Examination of a document in question may reveal it to be a forgery, on the evidence that the paper on which it is written was manufactured by a technique not available at the time to which it allegedly dates. The refractive index of even small particles of glass may be measured to show that a given item or fragment of glass was part of a particular batch manufactured at a particular time and place. Such information may help to identify the kind of automobile involved in a hit-and-run accident. Computer networks allow investigators to search increasingly large bodies of data on material samples, but the creation of the necessary data bases is a lengthy process.

MODUS OPERANDI AND SUSPECT IDENTIFICATION

The method by which an offense was committed may also help to identify the suspect, as many offenders repeatedly commit offenses in much the same way. The burglar's method of entry into the house, the type of property stolen, or the kind of deception practiced on the victim of a fraud may all suggest to the police who is responsible for the crime. Visual identification of a stranger by the victim is often possible, but experience has shown that such identifications are often mistaken and have frequently led to miscarriages of justice. If the victim or witness believes that he can recognize the offender, the police may show him an album containing photographs of a large number of known criminals, in the hope that one can be picked out. A suspect identified in this way is usually asked to take part in a lineup, in which the witness is asked to pick the suspect out of a group of people with similar characteristics.

GATHERING EVIDENCE

The identification of the suspect is not the final stage of the process: it is essential that the investigating agency gather sufficient legally admissible evidence to convince the judge or jury that the suspect is guilty before a conviction can be expected. It is common for the police to be

reasonably certain that a particular individual is responsible for a crime but to remain unable to establish his guilt by legally admissible evidence. In order to secure the necessary evidence, the police employ a variety of powers and procedures; because these potentially involve interference with the freedom of the suspect (who must at this stage be treated as an innocent person), they are normally subject to close control either by legislation or by the courts.

One important procedure is a search of the person of the suspect or of premises or vehicles. Most jurisdictions within the common-law tradition allow a search to be carried out only if there is "probable cause for believing" or "reasonable ground for suspecting" that the evidence will be found. In some cases a person may be stopped on the street and searched, subject to various requirements that the police officer identify himself and state the reasons for the search. A search of private premises usually requires a search warrant issued by a magistrate or judge. The law generally permits a search warrant to be issued only if the issuing authority is satisfied after hearing evidence on oath that there is good reason to suspect that the evidence, which the warrant usually defines specifically, will be found on the premises. The warrant may be subject to time limits and normally permits only one search to be carried out. In most countries the judge or magistrate who issues the warrant must be told of the outcome of the search. Material seized as a result of a search under the authority of a search warrant is usually detained by the police for production as exhibits at any subsequent trial. In the United States the law has imposed strict consequences on any abuse of this procedure; evidence discovered as a result of any search that does not comply with the procedures and standards laid down by the Supreme Court and by other courts, interpreting the various amendments to the U.S. Constitution collectively known as the Bill of Rights, is not admitted in the trial, even though it clearly establishes the guilt of the accused person, and even though the suppression of the evidence may prevent the conviction of a person who is plainly guilty. This rule, known as the exclusionary rule, has given rise to controversy in the United States and has not generally been adopted in other English-speaking countries.

The use of search warrants

INTERROGATION AND CONFESSION

The interrogation of suspected persons is an important aspect of the investigation of offenses. Usually the aim of the questioning is to obtain an admission of the offense that will lead eventually to a plea of guilty and avoid the need for a contested trial. All English-language countries place restrictions on the scope and methods of interrogation in order to ensure that suspects are not coerced into confessions by unacceptable means. In the United States any suspect who is being interrogated in custody must be offered the services of a lawyer, at the expense of the state if he cannot afford to pay, and failure to advise the suspect of this right (known as the Miranda warnings, after the case of *Miranda* v. *Arizona*) results in the rejection of a confession as evidence.

The Miranda warnings

English law follows the same general principle, that a person suspected or accused of a criminal offense is not at any stage in the process of investigation or trial obliged to answer any question or to give evidence. (There are a few minor exceptions; for instance, the owner of a motor vehicle is required by law to disclose the identity of the person who was driving the vehicle on any particular occasion, and drivers of motor vehicles may be required to give samples of breath, blood, or urine in certain circumstances.) For many years the law relating to confessions in England consisted of a simple rule prohibiting the admission as evidence at trial of any involuntary statement made by an accused person. This rule was supplemented by more detailed rules governing the questioning of suspected persons by the police, formulated by the judges of the High Court and known as the Judges' Rules. The principal effect of the Judges' Rules was to impose an obligation on the investigating police officer to administer to the suspect a caution to the effect that he was not obliged to answer any question and that anything he did say might be given in evidence at his trial. This caution was required to be given at the beginning of any period of interrogation and immediately before the suspect began to make a full statement or confession. Failure to give the caution at the right time or in the right form did not necessarily mean that the statement would be excluded from evidence, but it did give the trial judge the discretion to exclude the evidence if he considered it just to do so. The operation of the Judges' Rules was a source of controversy for many years, and they have been replaced by a comprehensive series of provisions under the Police and Criminal Evidence Act, 1984. This act provides that a confession by an accused person may be admitted in evidence provided that the court is satisfied that the confession was not obtained by oppression of the person who made it or as a result of anything said or done that was likely to render the confession unreliable. Oppression is defined to include torture, inhuman or degrading treatment, and the use or threat of violence, but there is no doubt that it includes other matters as well (such as excessively prolonged periods of questioning). This broad principle is supplemented by a much more detailed code of practice. For full treatment of trial procedures prior to sentencing, see the articles CRIMINAL LAW and PROCEDURAL LAW.

The Judges' Rules

Prosecution

In countries whose legal system follows the English tradition, the function of prosecution is usually distinguished from that of investigation on the one hand and adjudication on the other. In most countries (although not in England until recently) the function of prosecution has been given to an official who is not part of either the police or the judicial system; a wide variety of terms are used to designate this official—district attorney in the state jurisdictions of the United States, procurator-fiscal in Scotland, and crown attorney in Canada are examples. The prosecutor may be an elected local official (as in the United States in most cases) or a member of an organization responsible to a minister of the national government. The first tasks of the prosecutor are to assess the information collected by the investigators, to determine whether there is sufficient evidence to justify the institution of criminal proceedings, and to decide whether there are any reasons why the public interest requires that a prosecution should not be undertaken.

The prosecutor

In common-law systems the prosecutor is usually entrusted with extensive discretion in deciding whether to institute criminal proceedings. In part, this discretion arises out of the ambiguity of the criminal law; frequently a statute defining a particular criminal offense does not make absolutely clear what kind of behaviour it is intended to cover or includes a much wider range of circumstances than it was intended to prohibit. If this is so, the prosecutor must decide whether the case he is dealing with falls within what was intended to be the scope of the law. Changing attitudes in the community toward particular kinds of behaviour may mean that a criminal prohibition, while remaining on the statute books, no longer reflects the sentiment of the community, and the prosecutor is no longer expected to bring charges against people who infringe it. In other cases, laws may be enacted without the usual exemptions from responsibility for those who commit the act unintentionally (offenses of strict liability). In such cases the prosecutor may nevertheless feel justified in not bringing proceedings against those who are technically guilty if they are in his view morally innocent.

The court system

Court systems and procedures reflect the history and culture of the country in which they have developed; there are many variations among different countries, or among different jurisdictions within the same country, regarding the way in which criminal cases are brought to trial.

CRIMINAL PROCEDURE IN ENGLISH-SPEAKING COUNTRIES

Each state of the United States has its own legal system, and, within the United Kingdom, England and Wales, Scotland, and Northern Ireland all have different arrange-

ments for the conduct and procedure of criminal trials. These countries, however, generally follow what is called "adversarial" procedure, in which allegations are made by the prosecution, resisted by the defendant, and determined by an impartial trier of fact—judge or jury—who is generally required to find in favour of the defendant by acquitting him if there is any significant doubt as to his guilt. English criminal procedure, employing the adversarial method, is the model from which the court systems of many English-language systems have been developed (although Scotland evolved its own distinctively different rules independently); over the years the differences between, for instance, the English criminal courts and those of the typical U.S. state have widened in some aspects, but the same basic principles are still reflected in both countries. The court systems of most English-speaking countries provide two or more sets of criminal procedure, to deal with the more serious and less serious cases, and a further set of procedures for hearing appeals against the decisions of courts of trial. (See also JUDICIAL AND ARBITRATIONAL SYSTEMS.)

Adversarial procedure

England. All criminal cases brought to trial in England begin in the magistrates' court. The magistrates' court has a number of different functions to perform—to determine the mode of trial, to try the case if summary trial is chosen, and to deal with ancillary matters such as bail and the granting of legal aid. Although the expression "examining magistrates" is still found in the statutes, the magistrates have long ago lost any function in the investigation of the alleged crime; their function is now wholly concerned with the adjudicatory phase of the process. The police investigation is normally completed by the time the case comes before the magistrates' court for the first time. The magistrates themselves are for the most part laypeople chosen for their experience and knowledge of society. All are appointed by the central government on the advice of a committee (known as the Lord Lieutenant's Advisory Committee) for the particular county in which they are to sit. Magistrates, who are required to sit on an average of at least 14 days each year, develop considerable experience in their work, but they cannot be considered professionals. In large cities there are professional, legally qualified magistrates, known as stipendiary magistrates. The stipendiary magistrate can sit on his own, but lay magistrates may sit only as a bench of two or more. Lay magistrates are invariably attended by a legally qualified clerk to advise them on matters of law. The system of lay magistrates has existed in England and Wales since about 1360 and is generally an accepted part of the administration of justice.

Lay magistrates

The United States. Criminal procedure in U.S. states follows a pattern derived from English traditions and principles, but with many variations. The lay magistrates play an insignificant role, if any, in the U.S. system, and the prosecutor (the district attorney) is a key courtroom figure. He determines the charges, which in turn may well determine whether the accused appears before a lower court (dealing with misdemeanours) or a higher court (dealing with felonies). The accused is offered bail in almost every case, but he is not released unless he is able to deposit with the court either cash or security in the form of a bond, often posted on his behalf by a bondsman who charges a proportion of the amount of the bond. In some states it is common for an accused person to be released without bond on his own recognizance. The role of the examining magistrates in English criminal procedure may be played in the United States by the grand jury, whose task it is to examine the evidence produced by the prosecutor and, if warranted, to return an indictment. The deliberations and proceedings before the grand jury are normally conducted in private. When the case is brought before the trial court, it is often settled on the basis of a plea bargain made between the prosecutor and the defense lawyer, by which the accused pleads guilty to some of the charges and the prosecutor recommends a sentence that has been agreed upon beforehand. Plea bargaining, which can take many other forms, is more readily accepted in U.S. courts than in English courts as long as basic rules, designed to ensure fair dealing for the accused, are observed. If the case goes to trial before a jury, a major difference between the English and U.S. systems is seen in the procedure for the selection of the jurors. In a U.S. court the lawyers are allowed to question potential jurors about their beliefs and attitudes so as to exclude those who may be prejudiced. The selection of the jury in an important case may take almost as long as the hearing of the evidence. The rules of evidence are much the same as those followed in an English trial, with variations of detail, and the accused is normally represented by a lawyer paid for by the state if he cannot afford one himself. U.S. law allows a wider range of appeals, both within the state system and, if a question of constitutional rights is involved, by removal of the case to a federal court. It may be many years before the case is finally resolved beyond all dispute.

The grand jury

OTHER SYSTEMS OF CRIMINAL PROCEDURE

Continental Europe. The jurisdictions of continental Europe follow methods of criminal procedure very different from those of the English-speaking world. Often described as the inquisitorial method, continental practice emphasizes the role of the judge, who is normally responsible for calling and questioning all witnesses and who does not separate the process into two distinct phases of trial of guilt and sentencing. The tribunal may consist of several judges, or a combination of judges and lay assessors, who deliberate together on both conviction and sentence. The rules of evidence are generally less restrictive; materials that would be considered hearsay in common-law countries are often admitted, and information about the accused person's record is available to the tribunal. A major difference between the two traditions is that most European jurisdictions do not permit conviction on the basis of a plea of guilty; even though the accused is willing to admit his guilt, the court must investigate the evidence fully (although the admission is part of that evidence). A second major difference is that the decision of the tribunal is normally accompanied by a statement of reasons, which is never given for the verdict of a jury. (D.A.T.)

Inquisitorial method

An institution without parallel in English law is the French unified magistracy, whose members are divided into *assise* ("seated," or the members of the bench) and *parquet*, or *debout* ("standing," or the prosecuting attorneys). It is a state prosecuting system in which the state acts as a party to the prosecution of civil and criminal cases.

Africa. Prosecuting and sentencing systems in African countries in general follow those of the former colonial rulers from whom the legal systems are derived. In the common-law countries this means that, although there is everywhere state prosecution, considerable responsibility falls on the police forces to initiate prosecutions. Sentencing is the responsibility of the court that tries the case and convicts the defendant. In some countries, such as The Sudan and parts of Nigeria, where Indian legal influence was strong, versions of the Indian Criminal Procedure Code were adopted, in which the magistrate, rather than the police, takes charge of the investigation and levels charges.

Islāmic countries. Among Islāmic countries of English and French colonial heritage, the modern states have adopted the procedure of the colonial countries that ruled them. Pakistan, for instance, which originally inherited the Indian Criminal Procedure Code, now has a procedural system very similar to that of England. It is an accusatorial system in which both sides present their oral arguments to an impartial judge. There is a competent and independent bar from whose ranks judges are chosen. This was amended in 1980 with the introduction of special Islāmic courts and judges. On the other hand, Egypt's criminal system almost exactly mirrors that of France. The system is inquisitorial, and the judge has a much greater power to question and intervene and to determine the method of proceeding. There also exists the Niyaba, a system of state prosecutors very similar to the French *parquet*. Egyptian judges, unlike their English and Pakistani counterparts, are often career judges. In all categories of Islāmic states there are not only ordinary criminal courts but often also police courts, which tend to deal with lesser criminal offenses, and military courts, which hear questions affecting security and military matters. In those states, such as Saudi

Accusatorial system

Arabia and Iran, that claim to adhere totally, or almost so, to traditional Islāmic law, Islāmic judges, called *qāḍīs*, exercise jurisdiction in Islāmic courts.

China. The Chinese penal system broadly divides procedures and sanctions into criminal and administrative. "Crimes" are distinguished from "ordinary illegal acts." Crime is defined as behaviour punishable by a court under the criminal law or other laws calling specifically for criminal punishment for violators. Ordinary illegal acts can be punished administratively by nonjudicial bodies (such as the police) on their own initiative and according to less formal procedures. In general, administrative punishments cannot be appealed to a court.

The concept of circumstances

The concept of "circumstances" is crucial to criminal procedure in China, including the identity of the accused or the victim, the existence of an official campaign against the particular type of crime involved, or even matters such as whether a robber also beat his victim or showed repentance. Although many countries take such factors into account in sentencing, Chinese law differs by allowing circumstances to bring an act within or entirely outside the coverage of the criminal law and, more importantly, the associated criminal procedural law, the only type that provides for a public trial by a court and the right to a defense. In cases not subject to court proceedings, there is no right to a defense and no appeal to a court, but the maximum punishment that can be imposed is less severe.

(A.N.A./I.D.E./D.C.C./Ed.)

Sentencing

In countries following the Anglo-American legal tradition, sentencing is a function separate from the determination of guilt or innocence. Although in some U.S. jurisdictions juries determine the sentence, it is normally the responsibility of the judge. Most systems traditionally give judges considerable discretion in determining both the kind of penalty to be imposed (*e.g.,* imprisonment, fine, probation) and its severity. Such discretion has prompted complaints about disparities in the sentences given to different offenders and arbitrariness and idiosyncrasy in the decisions of individual judges. Many observers maintain that the sentence imposed on an offender depends more on the presiding judge than on the gravity of the offense.

Disparities in sentencing

Because of concerns about sentencing disparity, the federal system and a number of state systems in the United States have instituted sentencing guidelines, which prescribe narrow ranges of sentences and require judges to provide a written rationale if they sentence outside the guidelines. Many jurisdictions also have implemented mandatory sentences, which remove any judicial discretion.

Parole

In French the word *parole* means "word," and its use in connection with the release of prisoners was derived from the idea that they were released on their word of honour. The practice of allowing prisoners to be released from prison before serving their full sentence dates to at least 18th-century England. At that time almost all serious crimes (felonies) were punishable by death, but only a small proportion of offenders were actually executed. The majority of those sentenced to death were pardoned by the king, but their pardon was granted on the condition that they agree to be transported to a penal colony (*e.g.,* Australia or America for English prisoners, Africa, New Caledonia, and French Guiana for French convicts). Eventually the courts were given the power to pronounce sentences of transportation themselves, usually for a period specified in the sentence, but most sentences of transportation were modified by executive action. A system of "ticket of leave" developed in England, under which convicts detained under a sentence of transportation were allowed a measure of freedom or the right to return to England in return for good behaviour. When England abolished the sentence of transportation in the mid-19th century (French penal colonies continued to operate into the mid-20th century), it was replaced by penal servitude, which incorporated the same procedure under a different name, release on license. The prisoner sentenced to penal servitude could earn release from the penitentiary—but not from the shadow of the sentence—by his good behaviour in custody. Release was conditional on good behaviour outside prison; if another offense was committed, the prisoner could be returned to prison to serve out the rest of the sentence (known as the remanet). In England the system of release from sentences of penal servitude became almost inflexible by the late 19th century, with the result that all prisoners were released after serving a fixed and predetermined portion of their sentence. At the same time, the principle of indeterminate sentencing became widely accepted and eventually formed the basis of the sentencing laws of many jurisdictions in the United States.

Indeterminate sentence

In those states where indeterminate sentencing was adopted, the law required judges to fix maximum and minimum limits of confinement. The actual date of release was determined by a body usually known as the parole board, which had the power to revoke parole and return an offender to prison. Indeterminate sentences have a number of advantages. They allow authorities to observe the behaviour and attitudes of offenders, and in particular the way in which these change for the better. They also provide an incentive for a prisoner to improve his behaviour in order to convince the authorities that he is ready for release. In addition to contributing to the rehabilitation of offenders, indeterminate sentences have a number of administrative advantages. They are a powerful sanction against misbehaviour—prisoners who are violent or disruptive risk losing the chance for release—they enable the authorities to compensate for disparities in the sentences imposed by judges (often believed to be a source of friction and discontent among prisoners), and they provide a means by which the prison population can be kept within limits.

Beginning in the 1980s several U.S. states abolished parole, replacing it with determinate sentences that had a fixed release date ("truth-in-sentencing" laws). To retain some of the management advantages of parole, however, these states tended to increase "good time" provisions—generally capped at 15 percent of the imposed sentence—which allowed prisoners to reduce their sentence through good behaviour. Thus, these states abolished discretionary release and replaced it with a system determined by the sentence and the offender's behaviour in prison.

Parole supervision

An essential feature of parole is the supervision of the offender during the remaining part of the sentence after his release from prison. Prisoners who have been released on license are not free from all restrictions; they normally are required to observe various conditions, which may be quite restrictive and which may address such matters as where they live and work or require them to undergo medical or psychiatric treatment. Failure to comply with these conditions can lead to the revocation of the parole and a return to prison. Enforcement of the conditions, as well as the provision of assistance and counseling, is usually the responsibility of a probation or parole officer, to whom the paroled offender is required to report at stated intervals. In many countries the decision of the supervising officer or the parole board to return the offender to prison is not subject to appeal or judicial review, even though the consequences for the offender may be serious. However, there usually are regular due process procedures that must be followed to ensure a minimal level of fairness.

Theories and objectives of punishment

The objectives of punishment administered by the official organs of the state have been the subject of debate among philosophers, lawyers, and legislators for centuries. A variety of different theories or objectives of punishment have been proposed, some differing only in minor degrees, some fundamentally in conflict with each other.

RETRIBUTION

Retribution suggests that the severity of a punishment should be proportionate to the gravity of the offense. One theory of retribution maintains that punishment should never be imposed to achieve a social objective (such as law-abiding behaviour in the future by the offender or others

who witness his example). Rather, punishment should be an end in itself. Supporters of this view maintain that punishment must not be justified by its intended or actual results. It may have positive benefits for the offender or for the larger society, or it may have harmful effects, but neither of these is relevant. Instead, punishment is viewed as a morally mandated response to offending behaviour.

A second theory of retribution posits that retribution limits the punishments that may be imposed but that within those limits punishments may be used to accomplish particular goals or purposes. One variant of this principle is that punishment should not be inflicted unless a recipient has been found guilty of a specific offense, which would prohibit such practices as collective punishment imposed on whole communities or the taking of hostages from the general population. A second version maintains that the offender should not be punished more severely than the offense warrants and assumes that a scale can be drawn equating particular crimes with particular punishments. However, it is extremely difficult to devise such a scale without resorting to a crude system of inflicting on the offender exactly the damage he inflicted on the victim.

Retribution as a limiting principle

Retribution as a limiting principle can be distinguished from retribution as an educational principle. In the latter, enactment and implementation of the criminal law, and particularly the imposition of sentences, aims to provide a concrete example of society's values and to reinforce those values. Citizens who view that their moral values are expressed in a court's judgment may feel more strongly committed to them than previously; conversely, if they see them ignored by the court, they may question those values and feel less constrained by them. This principle assumes that a repeated failure of the courts to express such values undermines the legitimacy of the legal system and eventually leads to moral decline and the dissolution of society.

The educational principle is distinguished from the idea that the official organs of the state must punish offenders to satisfy the natural demand for punishment among members of the community, particularly among those who are the victims of the crime and who, in the absence of official punishment administered by the state, would seek revenge by direct violence. A variation on this interpretation of retribution is expiation—the idea that offenders should undergo punishment in their own interests to discharge their guilt and to make themselves acceptable to society again.

UTILITARIAN THEORIES

Utilitarian theories of punishment emphasize the deterrence of criminal behaviour and the consequences of punishment for individuals and society. Criminologists have identified several utilitarian theories, including those stressing general and individual deterrence.

General deterrence. General deterrence aims to dissuade others from following an offender's example and is not concerned with the future behaviour of the offender. Rather, it assumes that most crimes are rational and that potential offenders calculate the risk of being similarly caught, prosecuted, and sentenced. Demonstrating this theory's validity has proved difficult; general trends in crime and their relationship to particular sentencing policies are seldom an accurate indication of the effect of penalties as deterrents because there may be a variety of intervening factors. Occasionally it has been claimed that particular sentences have a strong deterrent effect, but this causal linkage is questionable. One example of effective general deterrence was legislation designed to curtail driving after drinking alcohol; studies have suggested that mandatory penalties and a high probability of conviction had at least a temporary deterrent effect on a wide population.

The deterrent effect of the death penalty

The death penalty has been claimed to have a general deterrent effect, but research in the United States has shown that some jurisdictions that have and use the death penalty have higher murder rates than those that do not. There are several interpretations of this pattern. Some argue that use of the death penalty is a response to, but not a cause of, high murder rates, but others maintain that it has a brutalizing effect that increases murder by instilling a lower regard for human life.

Individual deterrence. Individual deterrence is directed at the person being punished. It aims to teach the offender not to repeat the behaviour and is the rationale of much informal punishment, such as parental punishment of children. Theoretically, the effectiveness of individual deterrence can be measured by examining the conduct of the offender after the administration of the punishment to determine whether the offense was repeated. Such studies have often been misleading, however, because the only basis for determining that the offender repeated the offense was a further conviction. Because a high proportion of crimes do not result in convictions, many of those offenders who are not reconvicted after being punished in a particular way may have again committed offenses but avoided conviction or even arrest. Further, the general pattern of "aging out" of crime (*i.e.,* that criminal behaviour peaks in the late teens and early 20s and thereafter declines rapidly) is consistent with an individual deterrent effect and thus renders it difficult to reach definitive conclusions about the effectiveness of individual deterrence strategies.

Theories of deterrence and retribution share the idea that punishments should be proportional to the gravity of the crime, a principle of practical importance. If all punishments were the same, irrespective of the gravity of the crime, there would be no incentive to commit the lesser rather than the greater offense. The offender might as well use violence against the victim of a theft if the penalty for robbery was no more severe than that for simple stealing.

DENUNCIATION

The use of deterrence by some writers has coincided with the idea of retribution as a form of moral education for the community as a whole and has sometimes been described as denunciation. Although this idea was closely associated with general deterrence through fear, and many sentences of the courts were intended to achieve both objectives simultaneously, there was an important difference between them. Education through denunciation is generally aimed at law-abiding citizens who are not tempted to commit criminal acts. Its object is to reinforce their rejection of lawbreaking behaviour. Most people do not steal, because they know that stealing is dishonest; a sentence imposed on a thief reinforces their view. General deterrence through fear is aimed at those who do not necessarily reject the possibility of law-breaking behaviour on moral grounds but do so on the basis of a careful calculation of the gains and risks involved. Those who might consider stealing if they thought they could get away with it are frightened off by the example of the thief who is punished.

Deterrence through fear

INCAPACITATION

Incapacitation refers to making an individual "incapable" of committing a crime—*e.g.,* by execution or banishment historically, or in more modern times by execution or lengthy periods of incarceration. The only objective of punishment for which there is any certainty (although an incarcerated offender may escape from or commit crimes within the prison), incapacitation has often been difficult to reconcile with other principles, in particular those limiting retribution. In practice, incapacitation has been limited to offenders who have committed crimes repeatedly (multiple recidivists) under what are known as habitual offender statutes, which permit longer sentences for such offenders than are normally authorized for the offense, or to offenders who were designated as dangerous and likely to commit grave violent crimes unless restrained. Because it is difficult to identify such offenders with certainty, the principle is controversial.

REHABILITATION

Rehabilitation through treatment and training is a more recently formulated theory of punishment. Established in legal practice in the 19th century, it was viewed as a humane improvement on former practices, though it did not always result in the offender's receiving a more lenient penalty than a retributive or deterrent philosophy. For many offenders rehabilitation meant release on probation under some form of condition instead of a period in

prison; for others it meant a longer period in custody undergoing treatment or training than would have been acceptable if the punishment had been intended as retribution or as a deterrent. One popular expression of rehabilitation in the United States was an indeterminate sentence, under which the length of detention was governed by the degree of reform exhibited.

Criticism of rehabilitation

Beginning in the 1970s rehabilitation came under considerable criticism, largely because of the failure to demonstrate its success. However, research in the 1980s and '90s established that a wide variety of carefully implemented rehabilitation programs could reduce the recidivism of offenders. A second objection to rehabilitation was that sentences typically gave considerable authority to administrators. Many administrators were empowered to decide to release or to continue to detain the offender, depending on an assessment of the offender's progress, which was often vaguely defined. There have been cases in which this practice led to gross abuse and the detention of offenders guilty of minor crimes for long periods out of all proportion to the gravity of their offenses. (D.A.T./Th.B./Ed.)

THEORIES IN CONFLICT

In the practical operation of a sentencing or penal system, theories of punishment often come into conflict. A lenient sentence (such as probation) designed to rehabilitate an offender may fail to express society's rejection of the criminal behaviour or provide an effective deterrent to others; a sentence that requires the offender to submit to a compulsory program of treatment or training for a long period may conflict with the idea of retribution as a limiting principle; a sentence of unusual severity, designed to make an example of the offender as a warning to others, conflicts with the principles of rehabilitation and proportionality; and a sentence whose object is incapacitation may fail to satisfy those who favour rehabilitation and proportionality. The operation of any sentencing system requires decision makers to choose among these different theories in different cases; no single theory provides a system suitable for all cases. (D.A.T./Ed.)

PUNISHMENT IN OTHER SYSTEMS

Africa. Sentencing courts in Africa generally have stressed the punitive and deterrent rather than the reformative aspects of sentencing. Consequently, prison sentences usually are proportionately longer and fines heavier than in Europe. Legislation in African countries has reflected the same approach to sentencing; capital punishment and corporal punishment are permitted and in some cases mandatory. A notable feature of the Tanzanian legal system is the imposition of minimum sentences for a variety of offenses, including dishonesty and theft of stock. In practice the court had no option but to impose a specified minimum prison sentence, which at times included caning as part of the punishment.

Ḥadd crimes

Islāmic countries. Traditional Islāmic law divides crimes into two general categories. Several serious crimes, known as *ḥadd* crimes, are specifically mentioned, along with their appropriate penalties, in the Qurʾān. For example, the *ḥadd* punishment for theft was the amputation of a hand. As these crimes were considered offenses against the law of Allāh, the Qurʾān allowed no discretion in applying these punishments, either by judges or by any other governmental official, even in the interests of mercy. Most other crimes are called *taʿzīr* crimes (discretionary crimes), and their punishment is left to the discretion of the *qāḍī* (judge), though Sharīʿah law limits his discretion to certain traditional punishments. The traditional requirement of eyewitnesses—especially in the *ḥadd* crime of adultery, which requires four witnesses—has limited the application of the severest penalties. A recent innovation has been the imposition of fines. General punishments include imprisonment and corporal punishment.

China. The chief goal of criminal punishment in communist China has been reform. An authoritative Chinese textbook on criminal law states that the goal of reform in criminal punishment is founded upon the historical mission of the proletariat to reform society and mankind. The thoughts of citizens are not their own affair; the government has the right and the duty to ensure that all members of society become "new men." The commission of a criminal act is evidence that the offender is in particular need of reform and justifies the use of particularly coercive measures. The notion that an offender incurs a debt to society that can be paid merely by serving a prison term is alien to Chinese penology. The state is keenly interested in changing the offender's thinking during imprisonment. Thus, reform through labour and political study generally accompanies imprisonment.

The primacy of reform over deterrence is intimately connected with Chinese theories on the causes of crime. Chinese criminology posits that crime can be reduced and eliminated through thought reform, education, and the perfection of socialist society. Criminal punishment is seen as merely a supplementary means to this end. According to this view, when the thought of all members of society has been reformed, crime will cease.

Treatment of juvenile offenders

The juvenile justice system is composed of a series of laws, policies, and procedures designed to regulate the processing and treatment of nonadults for violations of law and to provide legal remedies protecting their interests in situations of conflict or neglect. Offenses committed by juveniles that are also criminal for adults are referred to as delinquency (*e.g.,* murder, robbery, larceny), whereas activities mandating legal intervention only for nonadults are referred to as status offenses (*e.g.,* alcohol and tobacco use, truancy, running away from home, etc.). Children generally are also subject to specialized laws, procedures, and policies designed to protect their interests when parents or other legal guardians are unavailable, negligent, or involved in custodial disputes.

Juvenile status offenses

The specific mechanisms for administering juvenile justice have varied over time, among societies, and even between jurisdictions within countries. The concept of delinquency as well as special trials and institutions for confining and controlling youth was established by the mid-19th century in England. Courts there had acquired the authority to intervene as "parent of the land" (*parens patriae*) to protect the property rights of children, and this legal concept was expanded as a foundation for special proceedings or outcomes for juveniles.

The juvenile court, sometimes called children's court or family court, was first established in 1899 in Chicago. Similar courts were created in rapid succession in other states, and the same model was implemented in many other countries (*e.g.,* Canada in 1908; England in 1908; France in 1912; Russia in 1918; Poland in 1919; Japan in 1922; and Germany in 1923). The reformist philosophy instituted in the juvenile court stressed probation (conditional release to parents or guardians) and resolution of family problems presumed to be reflected in delinquent behaviour. Detention centres specifically for juveniles were to replace jails as the primary forms of temporary secure confinement during the processing of cases. Imprisonment was avoided whenever possible, and court proceedings were to be nonadversarial, operating "on behalf of," rather than against, the juvenile. It was widely agreed that the emphasis on probation and family treatment was innovative but that the new system also expanded state control or regulation of the behaviour of youth via the creation of status offenses. Moreover, confinement and imprisonment in a detention centre or reformatory (subsequently renamed "training school") persisted as common outcomes, especially for disadvantaged youth.

Development of detention centres

A controversial method of juvenile punishment has been the use of corporal (physical) punishment. Although it is prohibited in many Western countries, it is still used in some parts of the United States and in much of the non-Western world. In the United States in the 1980s and '90s, rising juvenile crime led to increasing calls for the reinstatement of corporal punishment in those areas that had prohibited it. Opponents of corporal punishment have argued that it is inhumane and that it actually reinforces the delinquency of those who receive it.

IN ENGLAND

Early common law made no special provision for children who committed crimes. Provided that the child was over the minimum age for criminal responsibility (originally seven) and had "mischievous discretion" (the ability to tell right from wrong), the child was fully liable as an adult to the penalties provided by the law. During the 19th century children who were liable criminally were regularly imprisoned, and there are records of children being hanged as late as the 1830s. In practice, however, age was treated as a mitigating factor that reduced the severity of the punishments that children received compared with adults. The need to treat juvenile offenders differently was recognized in the 19th century by the reformatory movement, which established training institutions for young offenders as an alternative to confinement in adult prisons. The creation of a special justice system for juvenile offenders—the juvenile court—gained ground in the early 20th century. Juvenile courts, which dealt with both criminal and noncriminal cases, were established in England under legislation enacted in 1908. The English juvenile court is essentially a magistrates' court, exercising the ordinary criminal jurisdiction of the magistrates' court over a limited age group of offenders from the age of 10 (the minimum age of criminal responsibility) to 17. (Those under 14 are designated "children," and those over 14 and under 17 are classified as "young persons.") Offenders aged 17 and over appear in the normal adult courts, though special sentencing provisions are applied to offenders under the age of 21.

The main difference between a juvenile court and an adult court in England is that the juvenile court can try a much wider variety of offenses. It deals with juveniles for any offense except homicide, though it is not bound to deal with a young person for a serious offense such as robbery or rape. On such charges, a young person can be committed to the Crown Court for trial in the same manner as an adult. A child also can be committed to the Crown Court for trial on a charge of murder or manslaughter. If charged jointly with an adult, a juvenile can be sent to an adult court for trial, though he is normally returned to the juvenile court for sentencing.

Care proceedings

In addition to its criminal jurisdiction, the juvenile court deals with children of any age up to 17 in what is called a care proceeding, which is based on the idea that the child is in need of care, protection, or control because one of a number of conditions is satisfied. These conditions include neglect or assault by parents but also include the fact that the juvenile has committed an offense. A juvenile who commits an offense can thus come before the juvenile court either in criminal proceedings or in care proceedings, though the court cannot take action in care proceedings unless it is satisfied that the juvenile is in need of care, protection, or control. This combination of two different roles in the juvenile court was a source of difficulty and controversy for many years, particularly because the court in its criminal jurisdiction was required by law to "have regard to the welfare of the child or young person" and, if satisfied that it was necessary to do so, to remove him from unsatisfactory surroundings for his own good, irrespective of the gravity of the offense. Thus, juveniles who appeared before the juvenile court charged with a minor offense could be removed from the care of their parents and possibly be required to reside in an institution (known as a community home), perhaps for a period of several years and possibly under conditions of security. Proposals to change the image of the juvenile court so as to minimize its criminal aspects and to emphasize its welfare role were enacted in 1969 but never fully implemented. Thus, the dual role of the juvenile court has been retained, but its authority has been transferred to some extent to an administrative body, the local authority. If the juvenile court makes a care order—in practice the most powerful sanction it has available—its effect is to transfer parental rights over the child to the local authority, and it is for the local authority to decide whether to allow the child to live at home with his parents (but subject to local authority control), to board the child with foster parents, or to require the child to live in a community home. The court has only a limited degree of control over this decision.

The care order is only one of the sanctions available to the English juvenile court and is used only in a minority of the cases that come before it. Another measure, the supervision order, places the juvenile under the general supervision of a social worker but sometimes requires participation in a wide range of organized, constructive activities as intermediate treatment. A supervision order can also include restrictive requirements prohibiting the juvenile from certain activities or a curfew in the form of a "night restriction," a requirement to remain at home during the evening for a specified period. Juveniles can also be fined (though the court usually orders the parent to pay the fine) or be ordered to pay compensation.

IN THE UNITED STATES

In the 19th century in the United States, as elsewhere, juveniles accused of criminal behaviour were tried in the same courts as adults, and it has been reported that approximately a dozen youths were executed for crimes committed before they turned 14. In response to cases of jury nullification, in which juries were reported to have acquitted youthful offenders against the evidence; growing opposition to integrating juvenile and adult prisoners; and the "House of Refuge" movement, which sought to reform juveniles, courts were established at the beginning of the 20th century to deal specifically with problems involving juveniles.

"House of Refuge" movement

In the United States, as in England, a high proportion of cases involving juvenile offenders is handled informally by means of cautions or counseling. The procedure followed in juvenile courts is distinct from that of criminal courts. The juvenile court was originally founded as a coercive social-work agency rather than as a criminal court. Thus, juvenile courts normally have not been concerned with determining guilt or innocence so much as with making a finding of fact—that the juvenile is, for one reason or another, legally subject to the jurisdiction of the court. This finding of fact is comparable to conviction at a criminal trial in an adult court and is generally referred to as an "adjudication." The adjudication of a juvenile as delinquent is the basis for a "disposition" comparable to sentencing, in which either freedom in the community under supervision or confinement in a correctional facility can be ordered. In keeping with what was seen as the juvenile court's role as a welfare tribunal rather than a court of criminal jurisdiction, procedural standards in the United States were formerly rather elastic. Most American juvenile courts, like their English counterparts, also deal with cases of neglect as well as criminal cases and status offenses, which in England would fall within the scope of care proceedings.

In most states juvenile courts have jurisdiction over juveniles who commit offenses before the age of majority (generally 18 years of age, though it is lower in some states). In most states, once the court has taken jurisdiction over a juvenile, that jurisdiction cannot extend past his 21st birthday—meaning that, regardless of the offense, juveniles are required to be released when they turn 21. A juvenile can be confined beyond his 21st birthday if he had been transferred to criminal court and tried as an adult, though the rules in most states prohibit the transfer of juveniles below a certain age. During the 1990s, owing to fears stemming from rising rates of violent juvenile crime, several states lowered the age at which juveniles could be transferred to adult criminal court. In some states juveniles as young as 10 can be tried as adults, and in other states youths of any age can be tried as adults for certain classes of offenses.

Dissatisfied with the perceived leniency of juvenile-court punishments, legislatures in virtually all states passed laws in the 1980s and '90s with the intent of cracking down on juvenile crime. These laws included a wide variety of mandatory transfer mechanisms for juveniles who committed certain serious crimes or who had prior records of committing such crimes. These laws included a wide variety of mandatory transfer mechanisms, by which juveniles tried in juvenile court who had committed certain serious crimes or who had a prior record of committing such crimes could be transferred to adult prisons after they turned 21. The pressure for tougher treatment of juvenile cases also resulted in the creation and proliferation of

Mandatory transfer mechanisms

prison-visitation programs and militaristic "boot camps," which sought to reform juveniles through shock methods. Such programs were very popular in the last two decades of the 20th century, but support began to erode when research showed either no advantage or higher levels of recidivism. Many states also incorporated juvenile records in the sentencing guidelines for criminal courts so that an adult offender who had a juvenile record would receive a longer sentence than one who did not, thus eliminating the widely believed notion that juvenile offenders get a "fresh start" with a clean record when they become adults.

Critics of juvenile court have argued that its invention substituted a new rhetoric emphasizing the rights of children, but that by ignoring constitutional protections the court did not serve the best interests of youth. There has been much disagreement, especially in the United States, over whether the informality of juvenile court helps or hurts children. Some critics have argued that crowded court calendars and incompetent judges have thwarted the court's purpose and that juveniles have been denied the rights commonly afforded criminal defendants, though there has been no corresponding relaxation of the severity of treatment. Numerous legal challenges to juvenile-court decisions have prompted criminal courts in the United States to extend some due-process rights to juveniles, most of which pertain to the "adjudication" hearing (*i.e.*, the hearing that determines the facts of the case). Juveniles now have the right to be notified of the charges against them, to cross-examine witnesses, to have an attorney present at the adjudication stage, and to be protected from double jeopardy and self-incrimination. However, they do not have the right to a jury trial, to bail, or to an attorney at other stages of the proceeding. The exercise of due-process rights by juveniles has tended to make the court's operations more adversarial. However, research on the actual workings of juvenile courts has shown that due-process rights continue to be disregarded in many cases.

(A.N.A./D.C.C./Ga.J./Ed.)

Prisons

Imprisonment as a form of punishment is a relatively modern concept. Until the late 18th century, prisons were used primarily for the confinement of debtors, of accused persons waiting to be tried, and of those convicted persons waiting for their sentences—death or transportation—to be put into effect. Although imprisonment was a sentence available to the courts in misdemeanour cases, these were only a small proportion of the cases tried. The normal task of the assize courts in England was expressed in the fact that they were known as courts of "general gaol delivery"—delivery meaning the release of prisoners (to liberty or execution) rather than their commitment to the jails. The holding of accused persons awaiting trial remains an important function of prisons. In England generally about one-fifth of the prison population is unconvicted or unsentenced, and in some European countries (notably Italy) the proportion of unconvicted prisoners has been as high as four-fifths. However, since the decline of capital punishment in the late 18th century, the prison also has been used as a place of punishment. The concept of the penitentiary was advocated in England during this period by the English philosopher Jeremy Bentham. At the same time, the United States established penitentiaries first in Pennsylvania and then in New York. The less frequent use of the death penalty and the abolition of transportation meant that a sentence of confinement had become the principal sanction for most serious crimes by the end of the 19th century.

Courts of "general gaol delivery"

DEVELOPMENT OF THE PENITENTIARY

The penitentiary developed in the late 18th century in part as a reaction to the conditions of the jails. Poor sanitation in English prisons caused widespread disease among prisoners, who were generally held without any segregation according to gender or classification. Outbreaks of "jail fever" occasionally killed not only the prisoners but also the jailers and even, on occasion, the judges and lawyers involved in their trials. Many prisoners in England were confined not in buildings but rather in the hulks of ships moored in the River Thames and elsewhere. In theory they were waiting to sail to Australia under a sentence of transportation, but in practice many of them served their entire sentences in the hulks and were released without ever leaving the country. The appalling conditions in many local prisons of late 18th-century England were exposed by the English penal reformer John Howard, who traveled throughout Britain and later Europe for the preparation of his book *The State of the Prisons in England and Wales* (1777). Reaction against the gross severity of the penal system of death and transportation and against the physical conditions of the jails led to the construction of "convict prisons" by the central government in England. Local jails remained under the control of local authorities until 1877, when the prison system of England and Wales was brought under central government control and administered by a body known as the Prison Commission.

"Jail fever"

The prison system that developed in the United States is more complex. Offenders sentenced by federal courts for crimes against the federal criminal code serve their sentences in federal penitentiaries managed by the federal government. However, the majority of offenders in custody serve their sentences in state or local institutions. These institutions form part of the state's penal system and usually consist of one or more state penitentiaries. The penitentiaries are often supplemented by a number of institutions offering a lower degree of security, such as prison camps or farms and local jails. The principal function of the jail is to hold persons awaiting trial, but short sentences (less than 12 months) usually are served in the local jail rather than the state penitentiary.

THE PRISON POPULATION

Concern over prison conditions has not diminished. Owing to the rapid growth in prison populations in most countries, problems of security and the protection of prisoners from violence on the part of other prisoners was compounded by the difficulties that arose from overcrowding. Most industrialized societies experienced a rapid increase in prison populations after World War II. In 1880 England's prison population stood at 32,000. After the prisons came under central government control, there was a long period of decline, probably the result of changes in sentencing laws and practices. By the end of World War I the daily average prison population had decreased to roughly 10,000, and it remained relatively stable during the interwar years. After World War II there was a period of steady increase that continued unabated for several decades. From a daily average figure of about 12,000 in 1945, the prison population grew despite a variety of legal changes designed to contain it. By the 1960s it had reached 30,000—the level of the 1880s—and by 1976 it had surpassed 40,000, notwithstanding the introduction of a parole system and suspended sentences. At the beginning of the 21st century the total prison population surpassed 60,000.

Rising prison populations

A similar trend occurred in the United States. A total of 250,000 persons were incarcerated in penitentiaries in 1975. At the beginning of the 21st century this figure exceeded 1,250,000. Taking into account the more than 600,000 people in local jails, the total number of people behind bars in the United States was nearly 2,000,000.

The opposite trend was observed in The Netherlands, where the prison population was halved from 1950 to 1975. By 1990, owing to shorter sentences for common offenses, there were fewer than 2,500 convicted offenders (in addition to another 3,000 awaiting trial) imprisoned in the entire country. However, when sentences were lengthened in the 1990s, the prison population increased to nearly 15,000 by the end of that decade. Among the few countries experiencing a decrease in prison population in the last decades of the 20th century was Finland, where shorter sentences and the increased use of parole and suspended sentences caused the number of people incarcerated to fall by two-fifths, to 2,500, during the 1990s.

Decrease in Finland's prison population

The general rise in prison populations has been attributed to a variety of factors. Most significantly, there was a marked increase in reported crime and in the number of offenders brought before the courts. In England both re-

ported crime and the number of persons convicted rose faster than the prison population.

There are many similarities in the composition of prison populations. Prisoners are predominantly male—men make up roughly 95 percent of the prison population in most countries—though the number of women in prison has been rising at a higher rate than the number of men. Prison populations are also relatively young; approximately three-fourths of those in custody are under the age of 30. The most common offenses for which prisoners are convicted are burglary, theft, violent crimes, and robbery.

Types of institutions

In most countries, prisoners are distributed among a variety of types of institution. In the United States, most prisoners serving longer sentences are held in state prisons, many of which are large maximum-security buildings that hold more than 1,000 offenders in conditions of strict security. Young offenders usually are detained in separate institutions, often designated under names that imply that their primary purpose is treatment or correction rather than punishment, and women normally are held in separate institutions. Some prisoners who are not considered a danger to the community are confined in low-security or open prisons.

Prisons are classified administratively as local or central. Local prisons serve a variety of purposes, including the detention of prisoners serving shorter sentences or awaiting trial or sentencing. The worst overcrowding generally has occurred in local prisons. Central prisons detain prisoners serving longer sentences. For security purposes prisoners are classified into a variety of categories, ranging from those who are likely to attempt escape and who would, if successful, pose a significant danger to the public to those prisoners who can be trusted to work in conditions of minimal security. Central prisons include maximum-security institutions; medium-security prisons, where the level of security is lower; and open prisons, where security is minimal and there is normally no obstacle to escape. Some European countries have developed a further category of institution that accommodates prisoners who are allowed to serve their sentences intermittently, usually over a series of weekends. Younger offenders in England (in the age group 16–21) were often held in Borstal institutions, which were named after the village in Kent where the first one was operated in the early part of the 20th century. For many years these institutions were admired as an example of practical rehabilitation through training, and similar institutions were adopted in many countries. However, disillusionment with the effectiveness of Borstal institutions led to their abolition in Britain in the 1980s and their replacement by youth custody centres. Detention centres, where young male delinquents serving sentences not exceeding four months are put through a program of vigorous discipline and physical activity popularly known as the "short sharp shock," are another distinctive feature of the English prison system. However, research has failed to show that it was an effective deterrent to further crime.

Borstal institutions

Prisons have been described as total institutions, which exert control over every aspect of a prisoner's life. In addition to daily routines such as mealtimes, times of rising and retiring, and bathing, many other aspects of the prisoner's life are subject to strict control. In part this control constitutes the deprivation of freedom that is the essence of imprisonment, and in part it is a necessary means of maintaining security, controlling the introduction of weapons or contraband substances, and preventing escapes. Most prisons limit the number of visits that a prisoner is entitled to receive from his family or friends. Generally only relatives and friends of the prisoner are allowed to visit, though adequate facilities must be available for visits by legal advisers if the prisoner is engaged in any litigation. Visits are normally held within the sight of an officer, and in some cases within his hearing. In many prisons visits are conducted with the prisoner sitting on one side of a table and his visitor on the other (usually with some partition between them), and the visitor is sometimes searched for contraband. In other prisons the visitor and the prisoner are allowed to meet in a room without any physical barrier but still in the sight of officers. Conjugal visits, in which the prisoner's spouse is allowed to stay with the prisoner for a period of several days, are not permitted in England but are allowed in some U.S. states and in some other countries. The correspondence of prisoners is limited and subject to censorship by prison authorities.

Prison control is maintained by a number of disciplinary sanctions, including the forfeiture of privileges, confinement within a punishment block or cell, or the loss of remission for good time (*i.e.*, reduction in the length of a sentence as a reward for good behaviour). The procedures for the imposition of sanctions on prisoners have been improved in both England and the United States, in part as a result of actions taken through the courts. Most prisons are governed by rules that set out a code of conduct and list prohibited behaviour; the code must be given to the prisoner on his arrival. Typically, prohibited behaviour includes mutiny and violence to officers, escaping or being absent from a required location, and possessing unauthorized articles. The rules also include one or more generally defined offenses (such as the English "offence against good order and discipline") that are vague and open to various interpretations. Disciplinary sanction can be imposed by the prison administrator or governor in minor cases, but the imposition of more serious sanctions (*e.g.*, loss of remission for good time) requires a formal disciplinary hearing that must follow the basic rules of procedure in a court of law.

Prisoners' rights

The idea that prisoners possess rights that must be protected by actions in the courts was developed particularly in the United States. Legal actions brought by prisoners under the provisions of the U.S. Constitution—notably the Eighth Amendment's prohibition of "cruel and unusual punishments" and the Fourteenth Amendment's guarantees of due process and equal protection of the laws—established that interference with the constitutionally guaranteed rights of prisoners by prison officials required special justification. In some cases, courts ordered state prison administrators to make major improvements in prison conditions and disciplinary procedures or to close down particular institutions, though not all of these decisions were enforced effectively. Prisoners appealing to the courts in England, which has no codified constitution, have relied on the general principles of administrative law, which required fair procedures by disciplinary bodies.

For many prisoners the worst pressures arise not from the prison authorities but from fellow prisoners, particularly in overcrowded institutions where supervision is limited. Some criminologists have claimed the existence of a prison subculture, which is opposed to the official hierarchy of the prisons, demands the loyalty of the prisoner, expects conformity to a series of informal rules, and enforces compliance by violence and social pressures. Rape and other sexual assault are also common in prison. Certain types of prisoners are particularly likely to be treated with violence by other prisoners, including those incarcerated for having committed sexual offenses against children and law-enforcement officers sentenced for corruption or similar crimes. In some systems, such offenders have been put in solitary confinement for their own protection. Racial conflict has been a major problem in many American prisons, and riots have occurred in prisons in many countries, usually as a result of grievances over the management of the prison, disparity in sentencing, conflicts between rival gangs, and the uncertainties of the parole system.

The death penalty

IN ENGLISH LAW

Death was formerly the penalty for all felonies in English law, though it was never applied as widely as the law provided. Many offenders who committed capital crimes were pardoned, usually on condition that they agreed to be transported (or to transport themselves) to what were then the American colonies; others were granted what was known as the benefit of clergy, by which offenders who could prove that they were ordained priests (clerks in Holy Orders) were allowed to go free, subject to possible punishment by the ecclesiastical courts. During medieval times the only proof of ordination was literacy, and it became customary by the 17th century to allow anyone convicted

Benefit of clergy

of a felony to escape the death sentence by giving proof of literacy. All that was required was the ability to read (or recite) one particular verse from Psalm 51 of the Bible, known as the "neck verse" (for its ability literally to save one's neck); most offenders learned the words by heart. To ensure that an offender could escape death only once through the benefit of clergy, his hand was burned by the authorities.

In 18th-century England, concern with rising crime led to the passage of many statutes extending the number of offenses punishable by death and abolishing the benefit of clergy. By the end of the 18th century, English criminal law contained about 200 capital offenses, though the application of the death penalty was extremely erratic. Judges in capital cases were entitled to reprieve the offender so that he could petition for mercy, but if he decided to "leave the offender for execution," the death sentence was normally carried out immediately without appeal after the closing of the assize. Many offenders convicted of capital crimes escaped the gallows as a result of reprieves and royal pardons, usually on condition of transportation, and many others were acquitted against the evidence because the jury was unwilling to see the death penalty applied in a minor case.

The arbitrary application of the death penalty in the late 18th and early 19th centuries led to demands for reform both from humanitarians and from those who were concerned with the effectiveness of the legal system and who argued that the penalty's severity and arbitrariness undermined its deterrent effect. Between 1820 and 1840 most capital statutes were repealed, and by 1861 only four offenses remained punishable by death—murder, treason, arson in a royal dockyard, and piracy with violence.

Public execution

Until the mid-19th century, executions in England were public. In London and other cities, they were attended by large crowds and were often followed by scenes of violence and disorder. Public opinion eventually turned against the idea of executions as public spectacles, and after 1868 they were carried out privately in prisons.

Although treason remained a capital crime in England—and persons convicted of treason were executed after both world wars—in practice the only capital crime for which criminals were executed was murder. (Arson in a royal dockyard ceased to be capital in 1971.) From the 1930s until the mid-1960s, reformers campaigned for the abolition of the death penalty for murder. One attempt nearly succeeded in 1947 and prompted the government to appoint a royal commission to consider abolition. Following the publication of the report by the Royal Commission on Capital Punishment in 1953, there were a number of controversial executions and a further parliamentary attempt to abolish the death penalty altogether. In 1957 Parliament enacted a statute restricting the death penalty to certain types of murder, known as "capital murders," which included murder in the course of theft, murder of a police or prison officer in the execution of his duty, murder by shooting or causing an explosion, and murder committed on a second occasion. All other murders were to be punished by a mandatory life sentence, though murderers sentenced to life imprisonment were eligible to be released during their sentence.

The operation of the system of capital murder created great dissatisfaction. The public viewed some executions as unjustified, and some types of murderers escaped the death penalty simply because of the method used to commit the crime (*e.g.*, deliberate poisoners were not subject to the death penalty, but the emotional murderer who had happened to seize a gun was). Another objection was the fact that liability to the death penalty might depend on a narrow question of law, such as whether a murder committed by a burglar escaping from the scene of the burglary occurred "in the course or furtherance of theft." These objections led to further lobbying for change, and in 1965 Parliament passed the Murder (Abolition of Death Penalty) Act, which abolished the death penalty for all murders and replaced it with a mandatory life sentence. Originally a five-year experiment, the legislation was extended permanently in 1969, though there have been several unsuccessful attempts to reinstate the death penalty for murder. Judges were given the power to recommend that the offender sentenced to life imprisonment not be released before he had served a certain minimum period. Northern Ireland retained the death penalty for murder until 1973. In the late 1990s Parliament abolished the death penalty for treason and piracy with violence.

(A.N.A./D.C.C./Ed.)

IN THE UNITED STATES

In the United States, where the existence of the death penalty has been primarily a matter of state law, capital punishment was never as widely applied as in 18th-century England, but it was permitted by many states for murder and in some states for offenses such as rape and kidnapping. Executions were fairly common; in the decade before World War II between 150 and 200 persons were executed each year. The number of executions subsequently declined to about 50 each year by the late 1950s. During the 1960s doubts grew about the constitutionality of the death penalty and particularly about whether it violated the prohibition of "cruel and unusual punishment" found in the Eighth Amendment to the Constitution or the requirement of the Fifth and Fourteenth amendments that all persons within the United States be afforded equal protection under the law. These doubts led to a complete cessation of executions for nearly a decade until the constitutional issues were settled. In 1972 the Supreme Court issued a decision, *Furman* v. *Georgia,* in which it controversially and somewhat confusingly ruled that, though the death penalty itself did not violate the Constitution, the manner of its application did because it was both "arbitrary and capricious." In particular, the decision held that the application of capital punishment was discriminatory because it was far more likely to be imposed on African Americans than on whites. The decision left uncertain the precise constitutional requirements for a valid death penalty statute, except that it required that the system for applying the death penalty not discriminate against any racial or other minority.

Cessation of the death penalty in the United States

In response to the ruling, some states enacted legislation making the death penalty mandatory for certain crimes, on the assumption that, if there was no discretion in the application of the penalty, there could be no question of discrimination. Other states adopted statutes that allowed the death penalty to be imposed only after a special hearing at which mitigating and aggravating factors would be considered, thus ensuring that discretion would be exercised in a systematic rather than an arbitrary manner. In a series of decisions in 1976, the Supreme Court eventually ruled that, though laws providing a framework for the structured exercise of discretion were constitutional, those making application of the death penalty automatic were not. Thus, the death penalty statutes of some states were upheld, and other states passed legislation consistent with the Supreme Court's ruling. By the end of the 20th century, nearly 40 states and the federal government had passed laws allowing for the death penalty for murder. Some states initially provided the death penalty for other crimes, such as rape, but these laws were ruled unconstitutional by the Supreme Court.

The first execution under the new legislation took place in 1977. At the end of the 1990s, more than 80 people were executed annually, roughly one-third of them in Texas. At the beginning of the 21st century, there were more than 3,500 inmates on death row, including approximately 50 women.

Death row

Beginning in the late 1990s, there was considerable debate about whether the death penalty should be imposed on the mentally impaired and on offenders who were juveniles at the time of their crimes. There was also much controversy over the use of DNA testing to prove the innocence or confirm the guilt of prisoners. In response to concerns that innocent people might be executed, some states began to consider death penalty moratoriums. One such moratorium was ordered in 2000 by the governor of Illinois, who noted that, though the state had executed 12 people from 1977 to 2000, 13 others had been released from death row in the same period after being exonerated by new evidence.

IN CONTINENTAL EUROPE

The death penalty for murder has been abolished in most western European countries, though several (*e.g.*, Spain, Belgium, Italy, and Greece) of them retained it into the 1990s. The fall of communism (1989–90) in eastern Europe and the Soviet Union and the subsequent transition to democracy led to the repeal of the death penalty in some countries (*e.g.*, the Czech Republic, Hungary, Romania, Slovakia, and Slovenia), though not in others (*e.g.*, Belarus, Russia, and Yugoslavia).

IN AFRICA AND THE MIDDLE EAST

Abolition of capital punishment in Africa

The death penalty has been retained by most states in the Middle East and Africa, though it was abolished during the 1990s in several African countries, including Angola, Djibouti, Mozambique, Namibia, and South Africa. After several years of de facto abolition, Bahrain and Libya resumed executions in the 1970s, and some African governments resorted to the death penalty for new classes of offenses, such as armed robbery. In the late 1990s the death penalty was regularly used in Saudi Arabia and Iran, and military coups in some African countries have led to the execution by firing squad of former government leaders and other prominent figures.

IN CHINA

Despite the penological ideal of reform, the death penalty has been widely administered in China, mostly occurring for murder, rape, and robbery. In 1981 the number of offenses carrying a possible death sentence was expanded to include theft, bribery, embezzlement, molestation, gang fighting, drug trafficking, pimping, and teaching criminal methods. The Criminal Procedure Law adopted in 1979 originally required that all death sentences be approved by the Supreme People's Court, China's highest judicial organ. However, in 1981 the requirement was removed in cases of murder, rape, robbery, and a number of other crimes (*e.g.*, breaching dikes) that involved danger to the public.

Some death sentences in China are for immediate execution and some for suspended execution, whereby the condemned is given a two-year reprieve. If a person shows evidence of reform and repentance, the sentence can be commuted at the end of the two years to a life sentence or to a fixed term of imprisonment. A distinctive feature of the death penalty in China has been the use of "mass sentencing rallies," in which condemned prisoners are paraded in public before their execution, to publicize exemplary cases. Although the Criminal Procedure Law provided that the execution itself not be public, this rule has not been universally observed. At the beginning of the 21st century approximately 1,000 people were executed annually in China. (A.N.A./D.C.C./Ed.)

"Mass sentencing rallies"

THE CONTINUING CONTROVERSY

Arguments for and against the death penalty have taken many forms. Those in favour of its retention or reintroduction for murder claim that it has a uniquely potent deterrent effect on potentially violent offenders for whom the threat of imprisonment is not a sufficient restraint; that death is the only penalty that adequately reflects the gravity of murder; that prolonged detention over decades is actually a harsher penalty than death; and that execution is the only certain method of preventing a murderer from committing more murders. They also have argued that incarcerating murderers in prison for long periods is uneconomical. Opponents maintain that there is no evidence that the death penalty is a more potent deterrent than the threat of a sentence of life imprisonment. Indeed, a United Nations study in 1996 concluded that research had "failed to provide scientific proof that executions have a greater deterrent effect than life imprisonment." Opponents of capital punishment also have maintained that the death penalty tends to be imposed in a discriminatory manner on the poor and on members of minority groups; that it creates the risk that an innocent person may be executed; that it prevents any possible rehabilitation of the offender; that it lowers the community and the state to the same level of behaviour as the criminal; that violence used by the state in the form of capital punishment breeds violence by criminals and brutalizes those who administer it; and that the death penalty distorts the administration of the criminal law and sensationalizes trials. Criminologists have never succeeded in producing convincing evidence to resolve these issues, and many of the arguments covered in the debate involve questions of morality and personal conviction that are not within the scope of empirical criminological research. (D.A.T./Ed.)

Alternatives to prison

In most criminal justice systems the majority of offenders are dealt with by means other than custody—by fines and other financial penalties, probation or supervision, or orders to make reparation to the community.

Fines

The most common penalty is the fine. In the 1980s in England, for example, about four-fifths of all defendants who were found guilty were fined. The fine is a simple penalty that avoids the disadvantages of many other forms of sentence. It is inexpensive to administer and does not normally have the side effects, such as social stigma and loss of job, that may follow imprisonment. However, there are some limitations to fines, including the problem that financial penalties are less burdensome for more affluent offenders than for less affluent ones. It has been suggested that in some cases the more affluent offender may be able to persuade the court to fine him in circumstances where other offenders would be sent to prison, thereby lessening respect for the legal system. Other problems have arisen when courts have had to deal with offenders who have no financial resources or with those whose incomes are too small to allow them to pay anything more than a derisory fine. Some countries, notably Sweden, have solved this problem by allowing the court to calculate the fine in terms of a number of days' earnings.

The problem of lack of means is related to that of the enforcement of fines. A significant number of offenders who are fined have to be brought back to court for nonpayment. If the court is satisfied that the offender has failed to pay as a result of willful neglect or culpable default and that other means of securing payment are unlikely to succeed, he may be committed to prison or his property can be seized and sold, including any funds he may have in a bank account (garnishee order). The length of time for which an offender may be committed to prison for deliberate nonpayment of a fine depends on the amount outstanding. In England roughly 1 percent of those who are fined are imprisoned for deliberate nonpayment of fines, though usually for very short periods (one to two weeks). If the offender is able to pay the amount outstanding, he can be immediately released, and if he pays a portion, the term of imprisonment can be reduced proportionately.

Restitution or compensation

Related to the fine is an order to pay restitution (in some countries termed compensation), which has been a popular alternative to punitive sentencing in some countries. However, there are several drawbacks, including the fact that more affluent offenders may receive favourable treatment from the court because of their ability to pay (*e.g.*, they may not be sent to prison so that they can earn the money with which to pay restitution to the victim) and the fact that such schemes have not helped all victims of crime. Only those victims of crime whose offender is caught, is convicted, and has the funds to pay restitution are likely to be recompensed. Even when an offender is ordered to pay restitution, it is often by installments over a long period. Victims of violent crimes in some countries—such as England, Australia, and Canada—are entitled to restitution from public funds, whether or not the offender is detected or is able to pay restitution himself. Generally this type of program is administered by a criminal-injuries compensation board, to whom the victim can present evidence of the violence and the extent of his loss. If the board is satisfied that the crime has occurred and that the claim is reasonable, the victim is compensated in a single payment, sometimes in a large amount (not exceeding £500,000 in Britain). However, this scheme too has a number of limitations: relatives of murdered people do not normally receive anything unless they were financially dependent on

the victim or the victim was a child under 17 (when a token amount is payable); nothing is paid if the total extent of the injury is less than a certain amount; and nothing is payable if the victim has a criminal record or in any way provoked the crime.

Probation and suspended sentence

There are ways of dealing with offenders that do not involve the payment of money. One is probation, a system that has taken many different forms in different jurisdictions but that essentially involves the suspension of an offender's sentence subject to the condition that he agree to supervision by a probation officer and that he comply with such other requirements as the court deems appropriate. If offenders obey the probation order and do not commit any further offense, usually no other penalty is imposed. Otherwise, they can be brought back before the court and punished for the original offense as well as any later one. In many U.S. states probation has been combined with a suspended sentence, which is the sentence the offender would have to serve if he broke the order. In England sentences are not fixed in advance, and the court has complete discretion if there is a breach by the offender. English law also allows suspended sentences of imprisonment for a specified period (not more than two years), on condition that the offender commit no further offense during the period of suspension. This is different from a probation order, as no supervision is required and no other conditions can be included in the order.

Offenders suffering from a mental illness may be committed to a mental hospital rather than a penal institution if the court is provided with appropriate medical evidence. Alternatively, the court can issue a probation order with a condition that the offender undergo psychiatric treatment. Most systems allow an offender detained in a hospital to apply to a mental-health review board, which can order release if it considers that detention is no longer justified.

Reparation

The concept of reparation, in which an offender must provide services to the victim or to the community, has gained in popularity in a number of jurisdictions. In England this has taken the form of the community service order, under which the court is empowered to order anyone convicted of an offense that could be punished with imprisonment to perform up to 240 hours of unpaid work for the community, usually over a period of not more than 12 months. In order that reparation orders not amount to a form of forced labour, it is required that the offender consent to the order before it is issued. Typically carried out during the leisure time of the offender under the direction of the probation service, the work varies depending on the area, the time of year, and the offender's abilities. In some cases it may involve heavy physical labour, but in others it may require such work as the provision of help to physically impaired people. Offenders completing the hours of work ordered by the court receive no further penalty, but if they fail to carry out the work without a reasonable excuse, they can be resentenced for the original offense. Although follow-up studies of offenders given community service orders have not shown that this method is more effective than other forms of sentence in preventing further offenses, it is widely considered a successful innovation and has been adopted in other countries. As with fines, community service has been less expensive to administer than imprisonment, less damaging to the offender and his family, and more useful to the community. The vast majority of offenders complete the order satisfactorily. Despite some doubts about whether its use weakens the deterrent effect of the criminal law, community service has become an established sentencing alternative.

Other alternatives to prison are based on the idea of preventing offenders from committing further offenses. The most familiar power of this kind is that of disqualifying an offender from driving a motor vehicle or from holding a driver's license. This power is available under the laws of most countries to deal with offenders who have committed serious driving offenses, such as driving while intoxicated, or repeated but less serious offenses, such as speeding. Other forms of disqualification are imposed on offenders convicted of particular types of crimes. For example, a fraudulent company director may be forbidden to participate in the direction of a company; a corrupt politician may be disqualified from holding public office; or a parent who sexually abuses his children may be deprived of parental authority over them. Finally, new technologies, such as electronic monitoring through ankle bracelets, have allowed probation and parole officers to restrict the movement of offenders even though they live in their own homes or in community correctional facilities.

Other alternatives to prison are more severe. For prisoners convicted of sexual offenses, some jurisdictions have imposed physical or chemical castration in addition to prison to prevent them from committing further sexual crimes. Caning is particularly common in Africa and Asia. In one controversial study, *Just and Painful: A Case for the Corporal Punishment of Criminals,* which was originally published in 1985, criminologist Graeme Newman argued that existing methods of punishment, including prison, were ineffective in reducing crime and that scientifically administered electric shocks could reform offenders and serve as a cost-effective method of punishing criminals.

Caning

Crime and social policy

Historically, support for crime policies largely has been based on beliefs about their predicted ability to reduce crime. In the 1970s in the United States, for example, rehabilitation was largely abandoned because of the widely held view that it did not reduce future criminal activity, and the death penalty was reinstated because of the pervasive sentiment that it did. Criminologists increasingly were able to test the beliefs with empirical research, which subsequently influenced crime policies. Their studies showed that in some jurisdictions where the death penalty was imposed frequently, such as the U.S. state of Texas, the rate of homicide was higher than in jurisdictions where it was not used. If jurisdictions retaining the death penalty did not eventually lower their homicide rates, according to criminologists, then the deterrent effect of the death penalty could be called into question, though it might still be supported on the basis of its retributive effects. In addition to punishment policies, criminologists also tested the effectiveness of various policing strategies. Influential research on police responses to domestic violence, for example, showed that arresting the offender tended to reduce future violence in most cases but to increase it in others. This research influenced the handling of domestic violence in many police departments. Criminologists have also studied the effectiveness of preventive crime policies. Many biological, psychological, and social factors increase the risks of engaging in criminal behaviour, and crime policies that focus on the reduction or elimination of such factors have been shown to have long-term effects. For example, several successful programs directed at high-risk (*e.g.,* low-income or unmarried) mothers have provided prenatal health care, home visits by nurses after the birth of the child, and parenting classes for the mother when the child is a toddler. Certain educational programs for high-risk children also have proved beneficial. Given the wide attention that studies of these and similar programs have received, it is likely that criminological research will play an increasingly important role in the development of future crime policies. (Th.B./Ed.)

BIBLIOGRAPHY

General works. General coverage of topics in crime and punishment and in criminology is provided in SANFORD H. KADISH (ed.), *Encyclopedia of Crime and Justice,* 4 vol. (1983); and MIKE MAGUIRE, ROD MORGAN, and ROBERT REINER (eds.), *The Oxford Handbook of Criminology,* 2nd ed. (1997). Helpful introductory texts include JAMES A. INCIARDI, *Criminal Justice,* 6th ed. (2000); JOEL SAMAHA, *Criminal Justice,* 5th ed. (2000); GEORGE B. VOLD, THOMAS J. BERNARD, and JEFFREY B. SNIPES, *Theoretical Criminology,* 4th ed. (1998); and LARRY J. SIEGEL, *Criminology,* 7th ed. (2000).

Criminal policy. Criminal policy considerations are the subject of SAMUEL WALKER, *Sense and Nonsense About Crime and Drugs: A Policy Guide,* 4th ed. (1998); and FRANKLIN E. ZIMRING and GORDON HAWKINS, *Crime Is Not the Problem: Lethal Violence in America* (1997, reissued 1999).

Crime detection and criminal procedure. Works on crime detection include JOE NICKELL and JOHN F. FISCHER, *Crime Science:*

Methods of Forensic Detection (1999); PETER WHITE (ed.), *Crime Scene to Court: The Essentials of Forensic Science* (1998); and RUDOLF VOM ENDE, *Criminology and Forensic Sciences: An International Bibliography, 1950–1980,* 3 vol. (1981–82). Criminal procedure is addressed in GREAT BRITAIN ROYAL COMMISSION ON CRIMINAL PROCEDURE, *Report* (1981); YALE KAMISAR *et al., Modern Criminal Procedure: Cases, Comments and Questions,* 9th ed. (1999), and *2000 Supplement to Ninth Editions: Modern Criminal Procedure, Cases, Comments, Questions: Basic Criminal Procedure, Cases, Comments, Questions, and Advanced Criminal Procedure* (2000). Sentencing is examined in MICHAEL TONRY and KATHLEEN HATLESTAD (eds.), *Sentencing Reform in Overcrowded Times: A Comparative Perspective* (1997); NORVAL MORRIS and MICHAEL TONRY, *Between Prison and Probation: Intermediate Punishments in a Rational Sentencing System* (1990); and PETER H. ROSSI and RICHARD A. BERK, *Just Punishments* (1997). Studies focusing on rehabilitation are FRANCIS T. CULLEN and BRANDON K. APPLEGATE (eds.), *Offender Rehabilitation: Effective Correctional Intervention* (1997); RUDOLPH ALEXANDER, JR., *Counseling, Treatment, and Intervention Methods with Juvenile and Adult Offenders* (2000); GLENN D. WALTERS, *Changing Lives of Crime and Drugs: Intervening with Substance-Abusing Offenders* (1998); and TODD R. CLEAR and HARRY R. DAMMER, *The Offender in the Community* (2000).

The death penalty is analyzed in JAMES R. ACKER, ROBERT M. BOHM and CHARLES S. LANIER (eds.), *America's Experiment with Capital Punishment: Reflections on the Past, Present, and Future of the Ultimate Penal Sanction* (1998); WILLIAM A. SCHABAS, *The Abolition of the Death Penalty in International Law,* 2nd ed. (1998); ROGER HOOD, *The Death Penalty: A World-Wide Perspective,* 2nd rev. and updated ed. (1996, reissued with corrections 1998); and ROBERT JOHNSON, *Death Work: A Study of the Modern Execution Process,* 2nd ed. (1997).

Prison. Prisons and parole are discussed in NORVAL MORRIS and DAVID J. ROTHMAN (eds.), *The Oxford History of the Prison: The Practice of Punishment in Western Society* (1995, reissued 1998); MARK COLVIN, *Penitentiaries, Reformatories, and Chain Gangs: Social Theory and the History of Punishment in Nineteenth-Century America* (1997, reissued 2000); ROBERT P. WEISS and NIGEL SOUTH (eds.), *Comparing Prison Systems: Toward a Comparative and International Penology* (1998); and JONATHAN SIMON, *Poor Discipline: Parole and the Social Control of the Underclass, 1890–1990* (1993). Crime victims are the subject of ANDREW KARMEN, *Crime Victims: An Introduction to Victimology,* 4th ed. (2001); LESLIE W. KENNEDY and VINCENT F. SACCO, *Crime Victims in Context* (1998); R.I. MAWBY and S. WALKLATE, *Critical Victimology: International Perspectives* (1994); and JOEL BEST, *Random Violence: How We Talk About New Crimes and New Victims* (1999). The relation between mental health and criminal justice is treated in DAVID WEBB and ROBERT HARRIS (eds.), *Mentally Disordered Offenders: Managing People Nobody Owns* (1999); JOHN MONAHAN and HENRY J. STEADMAN (eds.), *Violence and Mental Disorder: Developments in Risk Assessment* (1994); and JÁNOS BOROS, IVÁN MÜNNICH, and MÁRTON SZEGEDI (eds.), *Psychology and Criminal Justice: International Review of Theory and Practice* (1998). A controversial work that proposed the use of electroshock therapy as an alternative to prison is GRAEME NEWMAN, *Just and Painful: A Case for the Corporal Punishment of Criminals,* 2nd ed. (1995).

Juvenile justice. Juvenile justice is the subject of GARY F. JENSEN and DEAN G. ROJEK, *Delinquency and Youth Crime,* 3rd ed. (1998); BARRY C. FELD, *Bad Kids: Race and the Transformation of the Juvenile Court* (1999); FRANKLIN E. ZIMRING, *American Youth Violence* (1998, reissued 2000); DONALD J. SHOEMAKER (ed.), *International Handbook on Juvenile Justice* (1996); and HOWARD N. SNYDER and MELISSA SICKMUND, *Juvenile Offenders and Victims: 1999 National Report* (1999).

(Th.B./Ga.J.)

Organized crime. Organized crime is the focus of WILLIAM J. CHAMBLISS, *On the Take: From Petty Crooks to Presidents* (1978, reprinted 1982), a lively analysis of the interaction between gangsters, businesspeople, politicians, and labour racketeers; MICHAEL LEVI, *The Phantom Capitalists: The Organisation and Control of Long-Firm Fraud* (1981), a study of the criminal organization and techniques of bankruptcy fraud and of the impact of control measures upon them; MARY MCINTOSH, *The Organisation of Crime* (1975), a comparative and historical analysis of the way in which criminal organizations adapt to changes in law enforcement and the economy; PETER REUTER, *Disorganized Crime: The Economics of the Visible Hand* (1983), an examination of the structure and profitability of crime in the United States; JAMES B. JACOBS, CHRISTOPHER PANARELLA, and JAY WORTHINGTON, *Busting the Mob: United States v. Cosa Nostra* (1994), an account of law enforcement's efforts against organized crime in the United States; and EMILIO C. VIANO (ed.), *Global Organized Crime and International Security* (1999), which gives a global perspective.

White-collar crime. A seminal work analyzing white-collar crime is EDWIN H. SUTHERLAND, *White Collar Crime* (1949, reissued 1983), the reissue of which contains the names of corporations not printed in the original edition and an excellent introduction. Other works addressing white-collar crime include JOACHIM J. SAVELSBERG and PETER BRÜHL, *Constructing White-Collar Crime: Rationalities, Communication, Power* (1994), a discussion of conceptual issues; MICHAEL LEVI, *Regulating Fraud: White-Collar Crime and the Criminal Process* (1987), an overview of the political and economic impact of fraud in Britain; and M. DAVID ERMANN and RICHARD J. LUNDMAN (eds.), *Corporate and Governmental Deviance,* 5th ed. (1996), an overview of some of the more sensational cases, particularly of malpractice by U.S. corporations against owners, employees, customers, and the general public.

(Mi.L./Th.B.)

Terrorism. A general work dealing with modern terrorism is MARTHA CRENSHAW and JOHN PIMLOTT (eds.), *Encyclopedia of World Terrorism,* 3 vol. (1997). Some additional works that focus on contemporary terrorism are BRUCE HOFFMAN, *Terrorism and Weapons of Mass Destruction: An Analysis of Trends and Motivations* (1999); WALTER LAQUEUR, *The New Terrorism: Fanaticism and the Arms of Mass Destruction* (1999); and JEFFREY A. SLUKA (ed.), *Death Squad: The Anthropology of State Terror* (2000).

(Ji.B./Th.B.)

International perspectives. International crime and punishment is the subject of GREGG BARAK (ed.), *Crime and Crime Control: A Global View* (2000); JEROME L. NEAPOLITAN, *Cross-National Crime: A Research Review and Sourcebook* (1997); and RICHARD J. TERRILL, *World Criminal Justice Systems: A Survey,* 4th ed. (1999); PHILIP L. REICHEL, *Comparative Criminal Justice Systems: A Topical Approach,* 2nd ed. (1999); and CHARLES B. FIELDS and RICHTER H. MOORE, JR., *Comparative Criminal Justice: Traditional and Nontraditional Systems of Law and Control* (1996). PIERS BEIRNE and JOAN HILL (compilers), *Comparative Criminology: An Annotated Bibliography* (1991), is a useful resource for a wide range of material. Prison systems around the world are examined in ROBERT P. WEISS and NIGEL SOUTH (eds.), *Comparing Prison Systems: Toward a Comparative and International Penology* (1998).

(Th.B.)

Criminal Law

Criminal law, in a broad sense, is the body of law that defines criminal offenses, regulates the apprehension, charging, and trial of suspected persons, and fixes penalties and modes of treatment applicable to convicted offenders. Criminal law is only one of the devices by which organized societies protect the security of individual interests and assure the survival of the group. There are, in addition, the standards of conduct instilled by family, school, and religion; the rules of the office and factory; the regulations of civil life enforced by ordinary police powers; and the sanctions available through tort actions. The distinction between criminal law and tort law is difficult to draw with real precision, but in general one may say that a tort is a private injury while a crime is conceived as an offense against the public, although the actual victim may be an individual.

This article treats the principles of criminal law and the influence of the social sciences on criminal legislation and law enforcement. For treatment of the law of criminal procedure, see PROCEDURAL LAW. For the larger context of crime, criminal behaviour, and punishment, see CRIME AND PUNISHMENT.

The article is divided into the following sections:

Principles of criminal law

The traditional approach to criminal law has been that crime is an act that is morally wrong. The purpose of criminal sanctions was to make the offender give retribution for harm done and expiate his moral guilt; punishment was to be meted out in proportion to the guilt of the accused. In modern times more rationalistic and pragmatic views have predominated. Writers of the Enlightenment such as Cesare Beccaria in Italy, Montesquieu and Voltaire in France, Jeremy Bentham in Britain, and P.J.A. von Feuerbach in Germany considered the main purpose of criminal law to be the prevention of crime. With the development of the social sciences, there arose new concepts, such as those of the protection of the public and the reform of the offender. Such a purpose can be seen in the West German criminal code of 1975, which provides that the court "has to consider the consequences of the sentence upon the future life of the offender in society." In the United States, a Model Penal Code proposed by the American Law Institute in 1962 states that an objective of criminal law should be "to give fair warning of the nature of the conduct declared to constitute an offense" and "to promote the correction and rehabilitation of offenders." Since that time there has been renewed interest in the concept of general prevention, including both the deterrence of possible offenders and the stabilization and strengthening of social norms.

COMMON LAW AND CODE LAW

Important differences exist between the criminal law of most English-speaking countries and that of other countries. The criminal law of England and the United States derives from the traditional English common law of crimes and has its origins in the judicial decisions embodied in reports of decided cases. England has consistently rejected all efforts toward comprehensive legislative codification of its criminal law; even now there is no statutory definition of murder in English law. Some Commonwealth countries, however, notably India, have enacted criminal codes that are based on the English common law of crimes.

Comparisons of Anglo-American and continental European criminal law

The criminal law of the United States, derived from the English common law, has been adapted in some respects to American conditions. In the majority of the U.S. states the common law of crimes has been repealed by legislation. The effect of such statutes is that no person may be tried for any offense that is not specified in the statutory law of the state. But even in these states the common-law principles continue to exert influence, for the criminal statutes are often simply codifications of the common law, and their provisions are interpreted by reference to the common law. In the remaining states, prosecutions for common-law offenses not specified in statutes do sometimes occur. In a few states the so-called penal, or criminal, codes are simply collections of individual provisions with little effort made to relate the parts to the whole or to define or implement any theory of control by penal measures.

In western Europe the criminal law of modern times has emerged from various codifications. By far the most important were the two Napoleonic codes, the *Code d'Instruction Criminelle* of 1808 and the *Code Pénal* of 1810. The latter constituted the leading model for European criminal legislation throughout the first half of the 19th century, after which, although its influence in Europe waned, it continued to play an important role in the legislation of certain Latin-American and Middle Eastern countries. The German codes of 1871 (penal code) and 1877 (procedure) provided the models for other European countries and have had significant influence in Japan and South Korea, although after World War II the U.S. laws of criminal procedure were the predominant influence in the latter countries. The Italian codes of 1930 represent one of the technically most developed legislative efforts in the modern period. English criminal law has strongly influenced the law of Israel and that of the English-speaking African states. French criminal law has predominated in the French-speaking African states. Italian criminal law and theory have been influential in Latin America.

Movements for codification and reform

In the last few decades the movement for codification and law reform has made considerable progress everywhere. The American Law Institute's Model Penal Code stimulated a thorough reexamination of both federal and state criminal law, and new codes were enacted in most of the states. England has enacted several important reform laws (including those on theft, sexual offenses, and homicide), as well as modern legislation on imprisonment, probation, suspended sentences, and community service. Sweden enacted a new strongly progressive penal code in 1962. In West Germany (Federal Republic of Germany) a revised version of the criminal code was published in 1975 and subsequently often amended. In the same year a new criminal code came into force in Austria. New criminal codes have also been published in Portugal (1982) and Brazil (1984). France enacted important reform laws in 1958, 1970, 1975, and 1982, as did Italy in 1981 and Spain in 1983. Other reforms have been under way in Finland, The Netherlands, Belgium, Switzerland, and Japan. The Soviet Union's constituent republics began enacting revised criminal codes in 1960, as did Czechoslovakia and Hungary (1961), East Germany (German Democratic Republic), Bulgaria, and Romania (1968), and Poland (1969). After Yugoslavia became a federal state in 1974, a

number of local penal codes came into force in addition to the federal code of 1977.

Comparisons between the systems of penal law developed in the western European countries and those having their historical origins in the English common law must be stated cautiously. Substantial variations exist even among the nations that adhere generally to the Anglo-American system or to the law derived from the French, Italian, and German codes. In many respects, however, the similarities of the criminal law in all states are more important than the differences. Certain forms of behaviour are everywhere condemned by law. In matters of mitigation and justification, the continental law tends to be more explicit and articulate than the Anglo-American law, although modern legislation in countries adhering to the latter has reduced these differences. Contrasts can be drawn between the procedures of the two systems, yet even here there is a common effort to provide fair proceedings for the accused and protection for basic social interests.

SUBSTANTIVE CRIMINAL LAW

Substantive criminal law is composed of the following elements: the definitions of the types of offenses that are held to be punishable; the classification of crimes (as, for example, felonies and misdemeanours in the United States, or *crime, délit,* and *contravention* in continental law); the principles and doctrines applied to the judgment of crime that qualify the provisions of criminal legislation (such as self-defense, necessity, insanity, and so forth); and principles determining national jurisdiction over crimes with an international aspect (crimes committed by foreigners, nationals abroad, or on ships and aircraft outside the national territory and waters).

The definition of criminal conduct. *Legality.* The principle of legality is recognized in almost all civilized countries as the keystone of the criminal law. It is employed in four senses. The first is that there can be no crime without a rule of law; thus immoral or antisocial conduct not forbidden and punished by law is not criminal. The law may be customary, as in common-law countries; in most countries, however, the only source of criminal law is a statute (*nullum crimen sine lege,* "no crime without a law").

Second, the principle of legality directs that criminal statutes be interpreted strictly and that they not be applied by analogical extension. If a criminal statute is ambiguous in its meaning or application, it is often given a narrow interpretation favourable to the accused. This does not mean that the law must be interpreted literally, if to do so would defeat the clear purpose of the statute. The Model Penal Code of the American Law Institute incorporates a provision that has been enacted in some U.S. state laws. It recommends that its provisions be construed "according to the fair import of their terms," which comes closer to the European practice.

Defining the application of the law

Third, the principle of legality forbids the application of the law retroactively. In order that a person may be convicted, a law must have been in effect at the time the act was committed. This aspect of the principle is embodied in the ex post facto provisions of the U.S. Constitution and such international treaties as the European Convention for the Protection of Human Rights and Fundamental Freedoms (1950) and the International Covenant on Civil and Political Rights (1966).

Fourth, the language of criminal statutes must be as clear and unambiguous as possible in order to provide fair warning to the potential lawbreaker. In some countries statutes may even be considered inapplicable if they are vague.

Protection against double jeopardy. Legal systems generally include some restriction against prosecuting a person more than once for the same offense. In Anglo-American law the most difficult problems of double jeopardy involve the question of whether the second prosecution is for the "same" or a "different" offense. It is held that acquittal or conviction of an offense prohibits subsequent prosecution of a lesser offense that was included in the first. According to the U.S. Supreme Court in *Blockburger* v. *U.S.,* 284 U.S. 299, 304 (1932), the test to be applied to determine whether there are two offenses or only one is whether each provision requires proof of a fact that the other does not. In continental European law, on the other hand, the question is whether or not the second prosecution concerns the same "material fact" or "historical event," and the state cannot subject a person to a second trial for any offense arising out of the same factual situation.

A problem under the federal system of the United States is whether or not an offender may be prosecuted under both state and federal law for the same conduct (the specific offenses being different). A number of state laws have prohibited state prosecutions after acquittals or convictions in a federal court or in the court of another state for offenses involving the same conduct.

Statutes of limitation. All systems of law have statutes restricting the time within which legal proceedings may be brought. The periods prescribed may vary according to the seriousness of the offense. In German law, for example, the periods range from six months for breaches of administrative regulations to 30 years for crimes involving a life sentence. General statutes limiting the times within which prosecutions for crimes must be begun are common in continental Europe and the United States. In England there is no general statute of limitation applicable to criminal actions, although statutes for specific crimes frequently have included time limits.

Time restrictions

In many countries there are no statutes of limitation for particularly heinous offenses, including capital felonies in the United States and genocide and murder in Germany. In 1968 the UN General Assembly adopted a Convention on the Non-applicability of Statutes of Limitation on War Crimes and Crimes against Humanity, despite strong opposition among the majority of Western members on the ground that it was retroactive.

Requirements of jurisdiction. The jurisdiction of a court refers to its capacity to take valid legal action. Many governments claim jurisdiction over the acts of their own nationals, even when these acts have occurred abroad. Accordingly, most states decline any obligation to surrender their nationals to other countries. The constitutions of Brazil, Germany, and The Netherlands prohibit extradition of their nationals; and in other states extradition is prohibited by statute, as in Belgium, France, and Switzerland. The Italian constitution permits extradition of nationals only if it is agreed upon in international conventions.

In Anglo-American practice, on the other hand, the jurisdiction of the courts is generally limited to acts occurring in whole or part within the boundaries of the state. Nationals who commit crimes in foreign countries may be extradited, but only if required or authorized by treaty with the country concerned. Within the United States, jurisdiction over criminal conduct was formerly limited, under the common law, to acts occurring within the territorial limits of a particular state. Thus, if a person fired a bullet across a state line and killed someone in another state, sometimes only the latter state was considered to have jurisdiction. Many states have, however, by statute extended their jurisdictions to cover offenses in which either the relevant result or the relevant conduct, or even only part of it, occurred in the state. In addition, federal statutes confer jurisdiction on U.S. courts in cases involving treason, forgery of ship's papers, enticing to desertion from military service, bribery of a U.S. official, and other acts, even though the conduct occurred outside the national boundaries. The United States also claims jurisdiction over crimes committed on U.S. vessels and aircraft on or over the high seas.

Territorial restrictions

The Tokyo Convention on Offenses and Certain Other Acts Committed on Board Aircraft (1963) and the Hague Convention for Unlawful Seizure of Aircraft (1970) recognize that states have the right and even the duty of jurisdiction with respect to any crime committed upon aircraft bearing its national character.

The elements of crime. It is generally agreed that the essential ingredients of any crime are (1) a voluntary act or omission (*actus reus*), accompanied by (2) a certain state of mind (*mens rea*). An act may be any kind of voluntary human behaviour. Movements made in an epileptic seizure are not acts, nor are movements made

by a somnambulist before awakening, even if they result in the death of another person. Criminal liability for the result also requires that the harm done must have been caused by the accused. The test of causal relationship between conduct and result is that the event would not have happened the same way without direct participation of the offender.

Criminal liability may also be predicated on a failure to act when the accused was under a legal duty to act and was reasonably capable of doing so. The legal duty to act may be imposed directly by statute, such as the requirement to file an income tax return, or it may arise out of the relationship between the parties, as the obligation of parents to provide their child with food.

The mental element. Although most legal systems recognize the importance of the guilty mind, or *mens rea,* the statutes have not always spelled out exactly what is meant by this concept. The American Law Institute's Model Penal Code has attempted to clarify the concept by reducing the variety of mental states to four. Guilt is attributed to a person who acts "purposely," "knowingly," "recklessly," or "negligently." Broadly speaking, these terms correspond to those used in continental European legal theory. Singly or in combination, they appear largely adequate to deal with most of the common *mens rea* problems. Their general adoption would clarify and rationalize the substantive law of crimes.

Liability without mens rea. Some penal offenses do not require the demonstration of culpable mind on the part of the accused. These include statutory rape, in which knowledge that the child is below the age of consent is not necessary to liability. There is also a large class of "public welfare offenses," involving such things as economic regulations or laws concerning public health and safety. The rationale for eliminating the *mens rea* requirement in such offenses is that to require the prosecution to establish the defendant's intent, or even recklessness, would render such regulatory legislation largely ineffective and unenforceable. Such cases are known in Anglo-American law as strict liability offenses, and in French law as *infractions purement matérielles.* In German law they are excluded because the requirement of *mens rea* is considered a constitutional principle.

Public welfare offenses

There has been considerable criticism of statutes that create liability without actual moral fault. To expose citizens to the condemnation of a criminal conviction without a showing of moral culpability raises issues of justice. In many instances, the objectives of such legislation can more effectively be achieved by civil sanctions, as, for example, suits for damages, injunctions, and the revocation of licenses.

Ignorance and mistake. In most countries the law recognizes that a person who acts in ignorance of the facts of his action should not be held criminally responsible. Thus, one who takes and carries away the goods of another person, believing them to be his own, does not commit larceny, for he lacks the intent to steal. Ignorance of the law, on the other hand, is generally held not to excuse the actor; it is no defense that he was unaware that his conduct was forbidden by criminal law. This doctrine is supported by the proposition that criminal acts may be recognized as harmful and immoral by any reasonable adult. The matter is not so clear, however, when the conduct is not obviously dangerous or immoral; a substantial body of opinion would permit mistakes of law to be asserted in defense of criminal charges in such cases, particularly when the defendant has in good faith made reasonable efforts to discover what the law is. In West Germany the Federal Court of Justice in 1952 adopted the proposition that if a person engages in criminal conduct but is unaware of its criminality he cannot be fully charged with a criminal offense; this has since been incorporated as rule in the German criminal code. Law and practice in Switzerland are quite similar. In Austria mistake of law is a legal defense.

Responsibility. It is universally agreed that, in appropriate cases, persons suffering from serious mental disorders should be relieved of the consequences of their criminal conduct. A great deal of controversy has arisen, however, as to the appropriate legal tests of responsibility. Most legal definitions of mental disorder are not based on modern concepts of medical science, and psychiatrists accordingly find it difficult to make their knowledge relevant to the requirements of the court.

Definition of legal responsibility

Various attempts have been made to formulate a new legal test of responsibility. The American Law Institute's Model Penal Code has endeavoured to meet the manifold difficulties of this problem by requiring that the defendant be deprived of "substantial capacity either to appreciate the criminality of his conduct or to conform his conduct to the requirements of the law" as a result of mental disease or defect. This resembles the Soviet formulation of 1958, which required a mental disease as the medical condition and incapacity to appreciate or control as the psychological condition resulting from it. The same may be said of the German law, although the latter includes in mental illness such disorders as psychopathy and neurosis in addition to psychoses and provides for various gradations of diminished responsibility. Several U.S. jurisdictions, including federal law, have abandoned the volitional prong of the insanity test and returned to the ancient English rule laid down in *M'Naghten's Case,* 8 Eng. Rep. 718, 722 (1843). According to that case, an insane person is excused only if he did not know the nature and quality of his act or could not tell right from wrong. The English Homicide Act of 1957 also recognizes diminished responsibility, though to less effect. The act provides that a person who kills another shall not be guilty of murder "if he was suffering from such abnormality of mind . . . as substantially impaired his mental responsibility for his acts or omissions in doing or being a party to the killing." The primary effect of this provision is to reduce an offense of murder to one of manslaughter.

Intoxication is usually not treated as mental incapacity. Soviet law was especially harsh; it held that the mental-disease defense was not applicable to persons who committed a crime while drunk and that drunkenness might even be an aggravating circumstance. In German law, on the other hand, intoxication like any other mental defect is acceptable as a defense in criminal cases.

Mitigating circumstances and other defenses. The law generally recognizes a number of particular situations in which the use of force, even deadly force, is excused or justified. The most important body of law in this area is that which relates to self-defense. In general, in Anglo-American law, one may kill an assailant when the killer reasonably believes that he is in imminent peril of losing his life or of suffering serious bodily injury and that killing the assailant is necessary to avoid imminent peril. Some jurisdictions require that the party under attack must try to retreat when this can be done without increasing the peril. Under many continental European laws, however, the defendant may stand his ground unless he has provoked his assailant purposely or by gross negligence, or unless the assailant has some incapacity such as infancy, inebriation, mistake, or mental disease. Other situations in which the use of force is generally justifiable, both in Anglo-American law and in continental European law, include the use of force in defense of others, law enforcement, and protection of property.

Doctrine of necessity

The use of force may also be excused if the defendant reasonably believed himself to be acting under necessity. The doctrine of necessity in Anglo-American law relates to situations in which a person, confronted by the overwhelming pressure of natural forces, must make a choice between evils and engages in conduct that would otherwise be considered criminal. In the oft-cited case of *U.S.* v. *Holmes,* in 1842, a longboat containing passengers and members of the crew of a sunken American vessel was cast adrift in the stormy sea. To prevent the boat from being swamped, members of the crew threw some of the passengers overboard. In the trial of one of the crew members, the court recognized that such circumstances of necessity may constitute a defense to a charge of criminal homicide, provided that those sacrificed be fairly selected, as by lot. Because this had not been done, a conviction for manslaughter was returned. The leading English case, *Regina* v. *Dudley and Stephens,* 14 Q.B.D. 273 (1884),

appears to reject the necessity defense in homicide cases. In German or French courts, however, the defendants would probably have been acquitted.

In general the use of force may be excused if the defendant reasonably believed himself to be acting under duress or coercion, or to be carrying out military orders believed by the defendant to be lawful.

Some particular offenses. All advanced legal systems condemn as criminal the sorts of conduct described in the Anglo-American law as treason, murder, aggravated assault, theft, robbery, burglary, arson, and rape. With respect to minor police regulations, however, substantial differences in the definition of criminal behaviour occur even among jurisdictions of the Anglo-American system. Comparisons of the continental European criminal law with that based on the English common law of crimes also reveal significant differences in the definition of certain aspects of more serious crimes. Continental European law, for example, frequently articulates grounds for mitigation involving considerations that are taken into account in the Anglo-American countries only in the exercise of discretion by the sentencing authority or by lay juries. This may be illustrated with respect to so-called mercy killings. The Anglo-American law of murder recognizes no formal grounds of defense or mitigation in the fact that the accused killed to relieve someone of suffering from an apparently incurable disease. Many continental European and Latin-American codes, however, provide for mitigation of offenses prompted by such motives and sometimes even recognize in such motives a defense to the criminal charge.

Degrees of participation. The common-law tradition distinguishes four degrees of participation in crime. One who commits the act "with his own hand" is a principal in the first degree. His counterpart in French law is the *auteur* (literally, "author"), or *coauteur* when two or more persons are directly engaged. A principal in the second degree is one who intentionally aids or abets the principal in the first degree, being present when the crime occurs; this is comparable to the French concept of *complicité par aide et assistance,* although in some countries, as, for example, Germany, that have adopted a wider (more subjective) interpretation of the concept it includes the activity of *coauteurs.* In Anglo-American law one who instigates, encourages, or counsels the principal without being present during the crime is called an accessory before the fact; in continental law this third degree of participation is covered partly by the concept of *instigation* and partly by the above-mentioned *aide et assistance.* The fourth and last degree of participation is that of accessory after the fact, who is punishable because he receives, conceals, or comforts one known by him to have committed a crime so as to obstruct his apprehension or to impede his punishment. In continental legal systems this conduct has become a separate offense. Italian and Austrian law treat all participants in a crime as principals in the first degree, with the exception of accessories after the fact. The American Law Institute's Model Penal Code proposes the same simplifications.

Accessory before or after the fact

Conspiracy. Under the common law, conspiracy is usually described as an agreement between two or more persons to commit an unlawful act or to accomplish a lawful end by unlawful means. This definition is delusively simple, however, for each of its terms has been the object of extended judicial exposition. Criminal conspiracy is perhaps the most amorphous area in the Anglo-American law of crimes. In some jurisdictions, for example, the "unlawful" end of the conspiracy need not be one that would be criminal if accomplished by a single individual; but courts have not always agreed as to what constitutes an "unlawful" objective for these purposes. Statutory law in some American states, following the lead of the American Law Institute's Model Penal Code, have limited conspiracy offense to the furtherance of criminal objectives. The European codes have no conception of conspiracy as broad as that found in the Anglo-American legal system. In some of the continental European countries, such as France or Germany, punishment of crimes may be enhanced when the offense was committed by more than one person acting in concert.

In most countries the punishment of agreements to commit offenses, irrespective of whether the criminal purpose was attempted or executed, is largely confined to political offenses against the state. Some extension of the conspiracy idea to other areas has occurred, however. Thus in the Italian code of 1930 association for the purpose of committing more than one crime was made criminal. None of these continental European provisions, however, has the generality of the original Anglo-American concept. None, for example, condemns agreements to commit acts not otherwise criminal.

Attempt. In Anglo-American law there is a class of offenses known as inchoate, or preliminary, crimes because guilt attaches even though the criminal purpose of the parties may not have been achieved. Thus the offense of incitement or solicitation consists of urging or requesting another to commit a crime. Certain specified types of solicitation may be criminal, such as solicitation of a bribe or solicitation for immoral purposes, or inciting members of the armed forces to mutiny.

Inchoate offenses

The most important category of inchoate offenses is attempt, which consists of any conduct intended to accomplish a criminal result that fails of consummation but goes beyond acts of preparation to a point dangerously close to completion of the intended harm. The line between acts of mere preparation and attempt is difficult to draw in many cases. In continental European and some Anglo-American legal systems, attempt may also consist of conduct that would be criminal if the circumstances were as the actor believed them to be. A defense of "impossibility" is recognized only if the mistake is shown to be absolutely unreasonable. Unlike the law of some continental European countries, no defense has traditionally been granted to an offender who voluntarily desists from committing the intended harm after his conduct has reached a point beyond mere preparation. The American Law Institute's Model Penal Code and several American state codes, however, provide for an affirmative defense if it can be shown that the actor "abandoned his effort to commit the crime or otherwise prevented its commission, under circumstances manifesting a complete and voluntary renunciation of his criminal purpose."

Criminal law and the social sciences

Criminal law has been strongly influenced in the past century or two by the social sciences, especially criminology, sociology, and psychology. The empirical methods of the social sciences have been introduced into legal research and have done much to improve legislation and the courts' approach to sentencing, as well as the planning methods of law-enforcement agencies.

Behavioral norms. The fact that the crime rates in many countries have risen faster than the population has brought into question the relevance of the law itself and whether or not laws against crime actually have an influence on an individual's behaviour. Various large-scale inquiries have been made into the relation between law and civil order: in the United States, the President's Commission on Law Enforcement and Administration of Justice; in Europe, several research studies sponsored by the Council of Europe; in Germany, the hearings of the Criminal Reform Commission of the Bundestag. One conclusion emerging from these inquiries is that criminal legislation ought to be restricted to acts that pose a serious threat to public order and that can be effectively dealt with by the police, the courts, and various correctional institutions. The effort to punish all behaviour that is considered immoral or deviant, such as drunkenness, gambling, disorderly conduct, vagrancy, and petty sex offenses, simply multiplies the number of crimes without changing the norms of behaviour.

Criminal law and human behaviour

The effectiveness of statutes. Human conduct is determined by many factors that are not responsive to criminal statutes. Thus it appears that introducing or abolishing the death penalty does not have any appreciable effect on the murder rate. Much depends also on the way in which laws are enforced. Any inquiry into the effectiveness of criminal statutes must examine the way in which police,

attorneys, and the courts operate—for example, the manner in which they investigate suspects, gather evidence, instruct juries, and use their powers in "plea bargaining" and in sentencing.

The effectiveness of punishment. It is difficult to determine the extent to which punishment serves to deter convicted offenders from committing further crimes. Studies of the effectiveness of various forms of the treatment of criminals have led some researchers to the conclusion that "nothing works." In a more positive light, available studies seem to indicate that lenient penalties (such as fines, probation, suspended sentences) and severe measures are about equally effective in preventing future criminality. Accordingly, there has been an international trend away from custodial treatment. Short-term sentences are seen as particularly harmful because they tear the offender away from his family and occupation and expose him to criminal indoctrination in prison and to social obloquy after his release. Long-term sentences are also viewed with growing skepticism, despite more than 150 years of prison reform, because of the adverse side effects of even the best institutions. These ill effects include acclimatization to the prison atmosphere, association with prison subcultures, infantilism, mental illness, and in general a decline in fitness for responsible life in a free community. It is now considered preferable to treat the convicted criminal in open institutions if possible.

Treatment of mental deficiency and juvenile delinquency. A large area of criminal behaviour involving mental deficiency and diminished responsibility cannot be dealt with through sentencing that does not also serve to rehabilitate the offender. Mentally disabled offenders require hospitalization and psychiatric treatment; this is usually handled through the probation mechanism or by commitment to a hospital for the criminally insane. Similar problems arise in the case of crimes resulting from narcotics addiction; prison terms for addicts make no sense unless some effort is made to treat the underlying condition. The same applies to juveniles, who are generally dealt with through separate courts and sent to detention centres, training centres, and part-time homes. (H.-H.J.)

BIBLIOGRAPHY

General and comparative works. Classics in the field include JAMES FITZJAMES STEPHEN, *A History of the Criminal Law of England,* 3 vol. (1883, reissued 1964); LEON RADZINOWICZ, *A History of English Criminal Law and Its Administration from 1750* (1948–); JEROME HALL, *General Principles of Criminal Law,* 2nd ed. (1960); GEORGE P. FLETCHER, *Rethinking Criminal Law* (1978); and GLANVILLE WILLIAMS, *Textbook of Criminal Law,* 2nd ed. (1983).

General and introductory texts include WAYNE R. LAFAVE and AUSTIN W. SCOTT, JR., *Substantive Criminal Law,* 2 vol. (1986), a discussion of topics such as responsibility, justification, and crimes against person and property; RUPERT CROSS, PHILIP ASTERLEY JONES, and RICHARD CARD, *Introduction to Criminal Law,* 11th ed. (1988), a standard British introductory text; MARISE CREMONA, *Criminal Law* (1989); PETER W. LOW, *Criminal Law,* rev. ed. (1990); J.C. SMITH and BRIAN HOGAN, *Criminal Law,* 7th ed. (1992), an outstanding text on British law; THOMAS J. GARDNER and TERRY M. ANDERSON, *Criminal Law: Principles and Cases,* 6th ed. (1996); JOHN N. FERDICO, *Ferdico's Criminal Law and Justice Dictionary* (1992); JOHN M. SCHEB and JOHN M. SCHEB II, *Criminal Law and Procedure,* 2nd ed. (1994), discussing such issues as law and punishment and the organization of the criminal justice system; L.B. CURZON, *Criminal Law,* 7th ed. (1994); ANDREW ASHWORTH, *Principles of Criminal Law,* 2nd ed. (1995), a work that focuses on English law; JOSHUA DRESSLER, *Understanding Criminal Law,* 2nd ed. (1995), a comprehensive text covering such topics as burden of proof and principles of criminal punishment; MICHAEL JEFFERSON, *Criminal Law,* 2nd ed. (1995); and PAUL H. ROBINSON, *Fundamentals of Criminal Law,* 2nd ed. (1995).

Treatises on selected nations. Criminal law of various countries is discussed in JONATHAN BURCHELL and JOHN MILTON, *Principles of Criminal Law* (1991), for South Africa; J.M. HERLIHY and R.G. KENNY, *An Introduction to Criminal Law in Queensland and Western Australia,* 3rd ed. (1990), a discussion of the fundamentals and the changes that have occurred; TIMOTHY H. JONES and MICHAEL G.A. CHRISTIE, *Criminal Law* (1992), a basic outline of criminal law in Scotland; several works on Canadian law, including GRAHAM PARKER, *An Introduction to Criminal Law,* 3rd ed. (1987), with chapters on criminal-law history and the relationship between law and morals; ERIC COLVIN, *Principles of Criminal Law,* 2nd ed. (1991), an introductory text; ALAN W. MEWETT and MORRIS MANNING, *Mewett & Manning on Criminal Law,* 3rd ed. (1994), a document on the significant changes that have taken place in many areas; and DON STUART, *Canadian Criminal Law: A Treatise,* 3rd ed. (1995), an edition that includes recent decisions made by the Supreme Court of Canada; and, for Germany, JOHANNES WESSELS, *Strafrecht Allgemeiner Teil: die Straftat und ihr Aufbau,* 23rd rev. ed. (1993); and REINHART MAURACH and HEINZ ZIPF, *Strafrecht: Allgemeiner Teil,* 7th ed., 2 vol. (1987–89).

Works on substantive criminal law. IMRE A. WIENER (A. IMRE WIENER), *Economic Criminal Offences: A Theory of Economic Criminal Law* (1990; originally published in Hungarian, 1986), examines policies of state in both capitalist and socialist countries. K.J.M. SMITH, *A Modern Treatise on the Law of Criminal Complicity* (1991), focuses on English law but contains references to American and Commonwealth jurisdictions. CELIA WELLS, *Corporations and Criminal Responsibility* (1993), questions the application of general or criminal-law doctrines to corporations. RAIMO LAHTI and KIMMO NUOTIO (eds.), *Criminal Law Theory in Transition: Finnish and Comparative Perspectives* (1992), contains essays covering various aspects of criminal-law theory. DAVID L. BAZELON, *Questioning Authority: Justice and Criminal Law* (1987), is a collection of essays by a U.S. Court of Appeals judge. THOMAS MORAWETZ (ed.), *Criminal Law* (1991), discusses such topics as liberalism, economics, reason, and emotions in criminal law. M. CHERIF BASSIOUNI (ed.), *International Criminal Law,* 3 vol. (1986–87), deals with the crimes, procedures, and enforcement of international criminal law. R.A. DUFF, *Intention, Agency, and Criminal Liability: Philosophy of Action and the Criminal Law* (1990), is an introduction to some central legal and philosophical issues concerning criminal liability. DOUGLAS N. HUSAK, *Philosophy of Criminal Law* (1987), attempts to expose the inadequacies of criminal law and outlines the direction that revisions should take. SANFORD H. KADISH, *Blame and Punishment: Essays in the Criminal Law* (1987), contains contributions made by one of the leading American legal scholars. MICHAEL S. MOORE, *Act and Crime: The Philosophy of Action and Its Implications for Criminal Law* (1993), discusses the act requirement of criminal law, the morality that justifies such a requirement, and the metaphysical nature of the acts. STEPHEN SHUTE, JOHN GARDNER, and JEREMY HORDER (eds.), *Action and Value in Criminal Law* (1993), is a collection of essays that discuss the philosophical foundations of criminal law and legal doctrine. MICHAEL J. GORR and STERLING HARWOOD (eds.), *Controversies in Criminal Law: Philosophical Essays on Responsibility and Procedure* (1992), deals with liability and procedure. NICOLA LACEY, CELIA WELLS, and DICK MEURE, *Reconstructing Criminal Law: Critical Perspectives on Crime and the Criminal Process* (1990), examines criminal law in its social, historical, and procedural context by analyzing the processes that surround its creation, development, and application. ALAN NORRIE, *Crime, Reason, and History: A Critical Introduction to Criminal Law* (1993), is an introduction to North American law. ALAN R. WHITE, *Misleading Cases* (1991), argues that several criminal-law concepts have been misinterpreted and have led to mistaken decisions and bad judgments. JEREMY HORDER, *Provocation and Responsibility* (1992), focuses on the historical and philosophical underpinnings of the legal doctrine of provocation. PATRICK J. KNOLL, *Criminal Law Defences,* 3rd ed. (1994), covers issues such as exemptions, justifications, excuses, and procedural defenses; J.C. SMITH, *Justification and Excuse in the Criminal Law* (1989), also provides a useful discussion of these issues. LAWRENCE P. TIFFANY and MARY TIFFANY, *The Legal Defense of Pathological Intoxication: With Related Issues of Temporary and Self-Inflicted Insanity* (1990), offers a literature review and analysis of the topic.

Works in criminology and sociology. NORVAL MORRIS, *Madness and the Criminal Law* (1982), focuses on criminal responsibility and sentencing of the mentally ill. PAUL H. ROBINSON and JOHN M. DARLEY, *Justice, Liability, and Blame: Community Views and the Criminal Law* (1995), includes a general discussion of the proper role of community views in formulating legal doctrines, as well as original studies on a wide range of disputed legal issues. ROBERT F. SCHOPP, *Automatism, Insanity, and the Psychology of Criminal Responsibility: A Philosophical Inquiry* (1991), examines the psychological components of criminal responsibility and the role that psychological impairment should play in a theory of criminal liability. JOHN F. GALLIHER, *Criminology: Human Rights, Criminal Law, and Crime* (1989), contains chapters on the origins of the law and the administration of the criminal law in the United States. CHARLES W. THOMAS and DONNA M. BISHOP, *Criminal Law: Understanding Basic Principles* (1987), reviews fundamental legal theories, terms, and concepts. TONI PICKARD and PHIL GOLDMAN, *Dimensions of Criminal Law* (1992), discusses the politics of criminal law. (H.-H.J./Ed.)

The Crusades

Organized by Western Christians in response to centuries of Muslim wars of expansion, military expeditions known as the Crusades began in the late 11th century. Their objectives were to check the spread of Islām, to retake control of the Holy Land, to conquer pagan areas, and to recapture formerly Christian territories; they were seen by many of their participants as a means of redemption and expiation for sins. Between 1095, when the First Crusade was launched, and 1291, when the Latin Christians were finally expelled from their kingdom in Syria, there were numerous expeditions to the Holy Land, to Spain, and even to the Baltic; the Crusades continued for several centuries after 1291, usually as military campaigns intended to halt or slow the advance of Muslim power or to conquer pagan areas. Crusading declined rapidly during the 16th century with the advent of the Protestant Reformation and the decline of papal authority.

Approximately two-thirds of the ancient Christian world had been conquered by Muslims by the end of the 11th century, including the important regions of Palestine, Syria, Egypt, and Anatolia. The Crusades, attempting to check this advance, initially enjoyed success, founding a Christian state in Palestine and Syria, but the continued growth of Islāmic states ultimately reversed those gains. By the 14th century the Ottoman Turks had established themselves in the Balkans and would penetrate deeper into Europe despite repeated efforts to repulse them.

The Crusades constitute a controversial chapter in the history of Christianity, and their excesses have been the subject of centuries of historiography. Historians have also concentrated on the role the Crusades played in the expansion of medieval Europe and its economic, political, religious, and social institutions.

This article is divided into the following sections:

The Crusading movement and the first four Crusades

THE FIRST CRUSADE AND THE ESTABLISHMENT OF THE LATIN STATES

Background and context. Although still backward when compared with the other civilizations of the Mediterranean basin, western Europe had become a significant power by the end of the 11th century. It was composed of several kingdoms loosely describable as feudal. While endemic private warfare, brigandage, and problems associated with vassalage and inheritance still existed, some monarchies were already developing better-integrated systems of government. At the same time, Europe was feeling the effects of population growth that had begun toward the end of the 10th century and would continue well into the 13th century. An economic revival was also in full swing well before the First Crusade; forestlands were being cleared, frontiers pushed forward, and markets organized. Moreover, Italian shipping was beginning to challenge the Muslim predominance in the Mediterranean. Especially significant for the Crusade was a general overhaul of the ecclesiastical structure in the 11th century, associated with the Gregorian Reform movement, which enabled the popes to assume a more active role in society. In 1095, for example, Urban II was in a strong enough position to convoke two important ecclesiastical councils, despite meeting resistance from Henry IV, the German king, who opposed papal reform policies.

The European revival of the 11th century

Thus it was that in the closing years of the 11th century western Europe was abounding in energy and confidence. What is more, Europeans possessed the capacity to launch a major military undertaking at the very time the Seljuq Turks, one of several tribes on the northeastern frontier of the Muslim world who had embraced Islām in the 11th century, were beginning to move south and west into Iran and beyond with all the enthusiasm of a new convert.

The effects of religion. The Crusades were also a development of popular religious life and feeling in the West. The social effect of religious belief at the time was complex: religion was moved by tales of signs and wonders, and it attributed natural disasters to supernatural intervention. At the same time, lay people were not indifferent to reform movements, and on occasion they agitated against clergy whom they regarded as unworthy. A peace movement also developed, especially in France, under the leadership of certain bishops but with considerable popular support. The popes proclaimed the Peace of God and the Truce of God, designed to halt or at least limit warfare and assaults during certain days of the week and times of the year and to protect the lives of clergy, travellers, women, and cattle and others unable to defend themselves against brigandage. It is particularly interesting to note that the Council of Clermont, at which Urban II called for the First Crusade (1095), renewed and generalized the Peace of God.

It may seem paradoxical that a council both promulgated peace and officially sanctioned war, but the peace movement was designed to protect those in distress, and a strong element of the Crusade was the idea of giving aid to fellow Christians in the East. Tied to this idea was the notion that war to defend Christendom was not only justifiable but a holy work, and therefore pleasing to God.

Closely associated with this Western concept of holy war was another popular religious practice, pilgrimage to a holy shrine. Eleventh-century Europe abounded in local shrines housing relics of saints, but three great centres of pilgrim-

age stood out above the others: Rome, with the tombs of SS. Peter and Paul; Santiago de Compostela, in northwestern Spain; and Jerusalem, with the Holy Sepulchre of Christ's entombment. Pilgrimage, which had always been considered an act of devotion, had also come to be regarded as a more formal expiation for serious sin, even occasionally prescribed as a penance for the sinner by his confessor.

The importance of Jerusalem

Yet another element in the popular religious consciousness of the 11th century, one associated with both Crusade and pilgrimage, was the belief that the end of the world was imminent. Some scholars have discovered evidence of apocalyptic expectations around the years 1000 and 1033 (the millennium of the birth and Passion of Jesus, respectively), and others have emphasized the continuance of the idea throughout the 11th century and beyond. Moreover, in certain late 11th-century portrayals of the end of all things, the "last emperor," now popularly identified with the "king of the Franks," the final successor of Charlemagne, was to lead the faithful to Jerusalem to await the Second Coming of Christ. Jerusalem, as the earthly symbol of the heavenly city, figured prominently in Western consciousness, and, as the number of pilgrimages to Jerusalem increased in the 11th century, it became clear that any interruption of access to the city would have serious repercussions.

By the middle of the 11th century, the Seljuq Turks had wrested political authority from the ʿAbbāsid caliphs of Baghdad. Seljuq policy, originally directed southward against the Fāṭimids of Egypt, was increasingly diverted by the pressure of Turkmen raids into Anatolia and Byzantine Armenia. A Byzantine army was defeated and Emperor Romanus IV Diogenes was captured at Manzikert in 1071, opening Christian Asia Minor to eventual Turkish occupation. Meanwhile, many Armenians south of the Caucasus migrated south to join others in the region of the Taurus Mountains and to form a colony in Cilicia.

Seljuq expansion southward continued, and in 1085 the capture of Antioch in Syria, one of the patriarchal sees of Christianity, was another blow to Byzantine prestige. Thus, although the Seljuq empire never successfully held together as a unit, it appropriated most of Asia Minor, including Nicaea, from the Byzantine Empire and brought a resurgent Islām perilously close to Constantinople, the Byzantine capital. It was this danger that prompted the emperor, Alexius Comnenus, to seek aid from the West, and by 1095 the West was ready to respond.

Byzantine call for help

The turmoil of these years disrupted normal political life and made the pilgrimage to Jerusalem difficult and often impossible. Stories of dangers and molestation reached the West and remained in the popular mind even after conditions improved. Furthermore, informed authorities began to realize that the revived power of the Muslim world now seriously menaced the West as well as the East. It was this realization that led to the Crusades.

Alexius's appeal came at a time when relations between the Eastern and Western branches of the Christian world were improving. Difficulties between the two in the middle years of the century had resulted in a de facto, though not formally proclaimed, schism in 1054, and ecclesiastical disagreements had been accentuated by Norman occupation of formerly Byzantine areas in southern Italy. A campaign led by the Norman adventurer Robert Guiscard against the Greek mainland further embittered the Byzantines, and it was only after Robert's death in 1085 that conditions for a renewal of normal relations between East and West were reasonably favourable. Envoys of Emperor Alexius Comnenus thus arrived at the Council of Piacenza in 1095 at a propitious moment; and it seems probable that Pope Urban II viewed military aid as a means toward restoring ecclesiastical unity.

The Council of Clermont. The Council of Clermont convoked by Urban on November 18, 1095, was attended largely by bishops of southern France as well as a few representatives from northern France and elsewhere. Much important ecclesiastical business was transacted, resulting in a series of canons. Among them were one that renewed the Peace of God and another that granted a plenary indulgence (the remission of all penance for sin) to those who undertook to aid Christians in the East. Then the pope, a Frenchman, addressed a large crowd at a great outdoor assembly.

His exact words will never be known, since the only surviving accounts of his speech were written years later, but he apparently stressed the plight of Eastern Christians, the molestation of pilgrims, and the desecration of the holy places. He urged those who were guilty of disturbing the peace to turn their warlike energies toward a holy cause. He emphasized the need for penance along with the acceptance of suffering and taught that no one should undertake this pilgrimage for any but the most exalted of motives.

The response was immediate and overwhelming, probably far greater than Urban had anticipated. Cries of "Deus le volt" ("God wills it") were heard everywhere, and it was decided that those who agreed to go should wear a cross. Moreover, it was not only warrior knights who responded; a popular element, apparently unexpected and probably not desired, also came forward.

The era of Clermont witnessed the concurrence of three significant developments: first, there existed as never before a popular religious fervour that was not without marked eschatological tendencies in which the Holy City of Jerusalem figured prominently; second, war against the infidel had come to be regarded as a religious undertaking, a work pleasing to God; and finally, western Europe now possessed the ecclesiastical and secular institutional and organizational capacity to plan such an enterprise and carry it through.

Preparations for the Crusade. Following Pope Urban's speech, preparations began in both East and West. Emperor Alexius, who had doubtless anticipated the mustering of some sort of auxiliary force, apparently soon realized that he would have to provide for and police a much larger influx of warriors. In the West, as the leaders began to assemble their armies, those who took the cross sought to raise money, often by selling or mortgaging property, both for the immediate purchase of equipment and for the long-term needs of the journey.

As preparations were under way, several less-organized bands of knights and peasants, commonly known as the "People's Crusade," set out across Europe. The most famous of these, brought together by a remarkable popular preacher, Peter the Hermit, and his associate Walter Sansavoir, reached Constantinople after causing considerable disorder in Hungary and Bulgaria. Alexius received Peter cordially and advised him to await the arrival of the main Crusader force. But the rank and file grew unruly, and on August 6, 1096, they were ferried across the Bosporus. While Peter was in Constantinople requesting additional aid, his army was ambushed at Cibotus (called Civetot by the Crusaders) and all but annihilated by the Turks.

Peter the Hermit's preaching in Germany inspired other groups of Crusaders who also failed to reach Jerusalem. One of these groups, led by the notorious Count Emicho, was responsible for a series of massacres of Jews in several Rhenish towns in 1096. Traditionally recognized as an important turning point in Jewish and Christian relations in the Middle Ages—in fact, often cited as a pivotal moment in the history of anti-Semitism—these attacks occurred first in Speyer and then with increasing ferocity in Worms, Mainz, and Cologne. The Jews of these towns often sought, and sometimes received, the protection of the bishop or futilely took refuge in local homes and temples. Forced by the Crusaders to convert or die, many Jews chose death. In fact, there are accounts of the Jews committing suicide and even killing their children rather than converting or submitting to execution by the Crusaders. Though zealotry of this nature is not unique to Christianity, these massacres were horrific and did not go unnoticed even by fellow Christians. Indeed, some contemporary Christian accounts attributed the defeat of the People's Crusade to them. After the massacres, the Crusaders moved on to Hungary, where they were routed by the Hungarian king and suffered heavy losses Emicho, who may not have participated in all the pogroms, escaped and returned home in disgrace.

Massacres of the Jews

The main Crusader force, which departed in August 1096

Peter the Hermit leading the Crusaders, from "Abreviamen de las Estorias," 1311.

as Urban directed, consisted of four major contingents. A smaller, fifth force, led by Hugh of Vermandois, brother of King Philip I of France, left before the others but was reduced by shipwreck while crossing the Adriatic from Bari to Dyrrhachium (now Durrës, Albania). Hugh alone of this army survived to participate in events in the East. Godfrey of Bouillon, leader of the first large army to depart and duke of Lower Lorraine since 1087, was the only major prince from the German kingdom involved in the Crusade, though he and his associates largely spoke French. Joined by his brothers, Eustace and Baldwin, and a kinsman, Baldwin of Le Bourcq, Godfrey took the land route and crossed Hungary without incident. Markets and provisions were supplied in Byzantine territory, and, except for some pillaging, the army reached Constantinople without serious problems on December 23, 1096.

A second force was organized by Bohemond, a Norman from southern Italy. The son of Robert Guiscard, Bohemond was on familiar ground across the Adriatic, where he had fought with his father and was understandably feared by the Byzantines. However, he was 40 years old when he arrived at Constantinople on April 9, 1097, and determined to come to profitable terms with his former enemy.

The third and largest army was assembled by Raymond of Saint-Gilles, the count of Toulouse. At age 55, he was the oldest and most prominent of the princes on the Crusade, and he aspired and perhaps expected to become the leader of the entire expedition. He was accompanied by Adhémar, bishop of Le Puy, whom the pope had named as legate for the Crusade. Raymond led his followers, including a number of noncombatant pilgrims whom he supported at his own expense, across northern Italy, around the head of the Adriatic, and then southward into Byzantine territory. This large body caused considerable trouble in Dalmatia and clashed with Byzantine troops as it approached the capital, where Raymond arrived on April 21.

Meanwhile, the fourth army, under Robert of Flanders, had crossed the Adriatic from Brindisi. Accompanying Robert were his cousin Robert of Normandy (brother of King William II of England) and Stephen of Blois (the son-in-law of William the Conqueror). No king took part in the First Crusade, and the predominantly French-speaking participants came to be known by the Muslims as Franks.

Latin-Byzantine friction

The presence near Constantinople of massive military forces, numbering perhaps 4,000 mounted knights and 25,000 infantry, posed a serious problem for Alexius, and there was occasional disorder. Forced to consider imperial interests, which, it soon became evident, were different from the objective of the Crusaders, the emperor required each Crusade leader to promise under oath to restore to him any conquered territory that had belonged to the empire before the Turkish invasions and to swear loyalty to him while the Crusaders remained in his domain. Since there was never any plan for the Crusade to go beyond the far-flung borders of the old Roman Empire, this would effectively give all conquests to the emperor. Only Bohemond willingly took the emperor's oath. The others did so under duress, and Raymond swore only a lukewarm oath to respect the property and person of the emperor. Despite this, Raymond and Alexius became good friends, and Raymond remained the strongest defender of the emperor's rights throughout the Crusade.

From Constantinople to Antioch. Late in May 1097, the Crusaders and a contingent of Byzantine soldiers reached the capital of the Turkish sultanate, Nicaea (now İznik, Turkey), which surrendered to the Byzantines on June 19. The Crusader army left Nicaea for Antioch on June 26 and found crossing the arid and mountainous Anatolia difficult. At Dorylaeum, on July 1, 1097, Turks attacked the advance column of the Crusader army. Despite the heat and a rain of arrows, the Crusaders held their ground, and, when the rest of the army drew up, the Turks were routed. A major victory in open warfare had been achieved by cooperation between the separate Western contingents and the Greeks.

Further advance across Anatolia was even more arduous, and it was only after suffering many casualties, especially in the region of the Taurus Mountains, that the Crusaders arrived near Antioch on October 20. Meanwhile, Godfrey's brother Baldwin left the main army to involve himself in Armenian politics and then became ruler of Edessa. The first of the Crusader states, the County of Edessa would provide a valuable buffer against Turkish attacks on Antioch and other Christian territories.

One of the great cities of the Levant and one of the patriarchal sees of Christianity, Antioch was surrounded by an

Difficulties at Antioch

enormous circle of walls studded with more than 400 towers. Despite reinforcements and supplies from Genoese and English ships and later from the patriarch of Jerusalem, then in Cyprus, the siege proved long and difficult, and many died of starvation or disease. Spring brought the threat of counterattack by a relief force under Kerbogha of Mosul. The situation seemed so hopeless that some Crusaders deserted and attempted to return home. Among these was Peter the Hermit, who was caught and returned to the host, where he was quietly forgiven. Another deserter was the French knight Stephen of Blois, who was cut off from the main body of the army by Kerbogha's forces and judged, not unreasonably, that the Crusaders were doomed. On his way home, Stephen met Alexius, who was marching at the head of a Byzantine relief force, and convinced him that Antioch's cause was hopeless. The emperor's decision to turn back, however justified tactically, was a diplomatic blunder; when the Crusaders learned of the emperor's move, they felt free from any obligation to return the city to him.

Bohemond, meanwhile, proposed that the first to enter the city should have possession of it, provided the emperor did not make an appearance. The Norman had, in fact, already made contact with a discontented commander within, who proceeded to admit him over a section of the walls on June 3, 1098. The other Crusaders followed Bohemond into the dozing city and quickly captured it. Only the citadel held out.

Thus, Antioch was restored to Christian rule. The victory, however, was incomplete. Kerbogha arrived with an enormous Turkish army and completely invested the city, which was already very low on provisions. Once again, the situation seemed hopeless. Disagreements among the leaders persisted and were accentuated by arguments over the validity of the Holy Lance, which a Provençal priest found below the cathedral and insisted was the lance that, according to the Gospels, had pierced the side of Jesus Christ when he hung on the cross. Nonetheless, on June 28 the Crusader army moved out of the city. The Turkish forces were not of high quality and had only tenuous loyalty to Kerbogha. When they saw the size of the Crusader forces and the resolve of the men, the Turks began to flee. With the evaporation of Kerbogha's army, the citadel finally surrendered to Bohemond, and its garrison was permitted to leave. Rejoicing was tempered by a devastating epidemic that took many lives, including that of the legate, Adhémar of Le Puy, who, as the spiritual leader of the Crusade, had been a wise counsellor and a stabilizing influence whom the leaders could ill afford to lose.

The Crusade leaders then fell into violent disagreement over the final disposition of Antioch. Bohemond, who had been responsible for the capture of the city and then had led its defense, wanted it for himself. Raymond, however, insisted that it be returned to the emperor. Unable to come to terms, Bohemond and Raymond refused to march to Jerusalem, effectively stalling the Crusade. The leaders agreed to depart only after the rank and file threatened to tear down the walls of Antioch. On January 13, 1099, the army then set out for Jerusalem under the leadership of Raymond of Saint-Gilles. As they moved south, Tancred and Robert of Normandy and, later, Godfrey and Robert of Flanders joined them. Bohemond, ignoring his previous oaths, remained in Antioch.

The siege of Jerusalem. Not far from Beirut, the army entered the territory of the Fāṭimid caliphs of Cairo, who, as Shīite Muslims, were enemies of the Sunnite Seljuqs and the caliphs of Baghdad. In August 1098 the Fāṭimids had occupied Jerusalem. The final drive of the First Crusade, therefore, was against the Fāṭimids of Egypt, not the Seljuqs.

On June 7, 1099, the Christian army—by then considerably reduced to perhaps 1,200–1,500 cavalry and 12,000 foot soldiers—encamped before Jerusalem, whose governor was well-supplied and confident that he could withstand a siege until a relief force arrived from Egypt. The Crusaders, on the other hand, were short of supplies and would be until six vessels arrived at Jaffa (Yafo) and managed to unload before the port was blockaded by an Egyptian squadron. On July 8 a strict fast was ordered, and, with the Muslims scoffing from the walls, the entire army, preceded by the clergy, marched in solemn procession around the city, thence to the Mount of Olives, where Peter the Hermit preached with his former eloquence.

Siege towers were brought up to the walls on July 13–14, and on July 15 Godfrey's men took a sector of the walls, and others followed on scaling ladders. When the nearest gate was opened, Tancred and Raymond entered, and the Muslim governor surrendered to the latter in the Tower of David. The governor, along with his bodyguard, was escorted out of the city. Tancred promised protection in the Aqṣā Mosque, but his orders were disobeyed. Hundreds of men, women, and children, both Muslim and Jewish, perished in the general slaughter that followed.

Massacre in Jerusalem

The Crusaders, therefore, attained their goal three long years after they had set out. Against the odds, this struggling, fractious, and naïve enterprise had made its way from western Europe to the Middle East and conquered two of the best-defended cities of the time. From a modern perspective, the improbability of the First Crusade's success is staggering. For medieval men and women, though, the agent of victory was God himself, who worked miracle after miracle for his faithful knights. It was this firm belief that would sustain centuries of Crusading.

The Crusader states. A successful surprise attack on the Egyptian relief army ensured the Crusaders' occupation of Palestine. Having fulfilled their vows of pilgrimage, most of the Crusaders departed for home, leaving the problem of governing the conquered territories to the few who remained. Initially, there was disagreement concerning the nature of the government to be established, and some held that the Holy City should be ruled under ecclesiastical authority. As an interim measure, Godfrey was elected to govern and took the modest title of defender of the Holy Sepulchre.

In December 1099, in the midst of this confused situation, Bohemond and Baldwin of Edessa arrived in Jerusalem to fulfill their Crusader vows. Accompanying Bohemond was Daimbert, the archbishop of Pisa, who was chosen patriarch and received the homage of both Godfrey and Baldwin. If Daimbert had ambitions to govern Jerusalem, they were thwarted when, on Godfrey's death, his brother Baldwin was summoned back to Jerusalem, where he assumed the title of king (November 11, 1100). Thus, there had come into being not a church state but a feudal Kingdom of Jerusalem.

Securing the new Christian territories was now of utmost concern. The Crusade of 1101, for example, was organized by Pope Paschal II to reinforce Christian rule in the Holy Land, but it collapsed in Asia Minor. King Baldwin, however, profited nonetheless from the chronic rivalries of his Muslim neighbours. He was also able to extend his control along the coastline with the aid of Italians and in one instance of a Norwegian squadron that arrived under King Sigurd in 1110. By 1112 Arsuf, Caesarea, Acre, Beirut, and Sidon had been taken, and the entire coast except for Ascalon and Tyre was in Latin hands.

Meanwhile, castles had been built in Galilee, the frontier pushed southward, and Crusader states formed in the north. The County of Edessa, an ill-defined domain extending into the upper Euphrates region with a population consisting mainly of Armenians and Syrians, had already been established by Godfrey's brother Baldwin. When Baldwin left to become ruler of Jerusalem, he bestowed the county, under his suzerainty, on his cousin Baldwin of Le Bourcq.

Antioch had not been returned to the emperor, and Bohemond had consolidated his position there. The city was predominantly Greek in population, though there were also Syrians and Armenians, and the latent Greek-Latin friction was intensified when Bohemond replaced the Greek patriarch with a Latin one. When Bohemond was captured by the Muslims in 1100, his nephew Tancred became regent and expanded the frontiers of the principality to include the important port of Latakia, taken from the Byzantines in 1103. Not long after his release in 1103, Bohemond travelled to Europe, where he succeeded in winning over Pope Paschal II to the idea of a new Crusade. Whatever the original intention, there resulted not an ex-

pedition against Muslims but an attack on the Byzantine city of Dyrrhachium. Like its predecessor, the ill-fated campaign of 1082, the enterprise failed, and in 1108 Bohemond was forced to take an oath of vassalage to the emperor for Antioch and to return to Italy, where he died in 1111. Tancred, again in power, ignored his uncle's oath, and Antioch and its patriarchate remained a source of controversy.

A fourth Crusader state was established on the coast in the vicinity of Tripoli (Arabic: Ṭarābulus) by Raymond of Saint-Gilles, who had been outmaneuvered in Jerusalem and had returned to Constantinople hoping for aid from the Byzantine emperor to whom he had always been loyal. In 1102 he returned to Syria, took Tortosa (Ṭarṭūs), and began the siege of Tripoli. But he died in 1105, and it remained for his descendants to finish the task in 1109.

The establishment and protection of the frontier was, for the new states, a problem conditioned by geography and the politics of Levantine Islām. From Antioch south, the Crusaders held a narrow strip of coastland bounded by mountains to the north and by the Jordan Valley in the south. To the east beyond the Syrian desert lay the Muslim cities of Aleppo, Ḥamāh, Homs, and Damascus. Though the Franks did push southward to Aylah (or Elim, modern Al-ʿAqabah), all attempts to move eastward failed, and it was necessary to erect castles at vulnerable points along the eastern frontier as well as along the coast and inland. Among the most famous of these were Krak de Montréal, in the Transjordan, and Krak des Chevaliers, in the County of Tripoli. Meanwhile, the hostility between Shīʿite Egypt and Sunnite Baghdad continued for some time. The emirates in between the two powers remained divided in their allegiance, and those in the north feared the Seljuqs of Iconium.

Crusader castles

After Baldwin I's death in 1118, the throne passed to his cousin Baldwin of Le Bourcq (Baldwin II), who left Edessa to another cousin, Joscelin of Courtenay. In 1124 Tyre, the last great city north of Ascalon still in Muslim hands, was taken with the aid of the Venetians, who, as was customary, received a section of the city. Baldwin II was succeeded by Fulk of Anjou, a newcomer recommended by Louis VI of France. Fulk was married to Baldwin's daughter Melisende. In 1131 Baldwin and Joscelin both died. They were the last of the first generation of Crusaders, and with their passing the formative period in the history of the Crusader states came to an end.

Fulk's policies ended the pursuit of expansion and resulted in a stabilization of the frontiers of the Crusader states. This was a wise course, because his reign coincided with the rise of Zangī, *atabeg* (Turkish: "governor") of Mosul, whose achievements earned him a reputation as a great champion of the jihad (holy war) against the Franks. When Zangī moved against Damascus, the Muslims of that city and the Christians of Jerusalem formed an alliance against their common enemy, a diplomatic initiative that was common among the second-generation Franks.

The northern Crusader states, however, were in great danger. The Byzantines had recovered their influence in Anatolia and were putting pressure on Armenia and Antioch. Emperor Manuel Comnenus forced Prince Raymond of Antioch to acknowledge imperial suzerainty. But the greater danger to both Antioch and Armenia was dramatically brought home by Zangī's capture of Edessa in 1144. Attempts at recovery failed, and the northernmost Crusader state was subsequently overrun.

THE ERA OF THE SECOND AND THIRD CRUSADES

The Second Crusade. It had long been apparent that Edessa was vulnerable, but its loss came as a shock to Eastern and Western Christians. Urgent pleas for aid soon reached Europe, and in 1145 Pope Eugenius III issued a formal Crusade bull, *Quantum praedecessores*. It was the first of its kind, with precisely worded provisions designed to protect Crusaders' families and property and reflecting contemporary advances in canon law. The Crusade was preached by St. Bernard of Clairvaux in France and Germany. Bernard revolutionized Crusade ideology, asserting that the Crusade was not merely an act of charity or a war to secure the holy places but a means of redemption. Christ, in his mercy, offered the warriors of Europe a blessed avenue of salvation, a means by which they could give up all they had to follow him.

As in the First Crusade, many simple pilgrims responded. Unlike the First Crusade, however, the Second was led by two of Europe's greatest rulers, King Louis VII of France and Emperor Conrad III of Germany. Louis enthusiastically supported the Crusade, but Conrad was reluctant at first and was won over only by the eloquence of St. Bernard. The Second Crusade also differed from its predecessor in that there were three objectives instead of one. While the kings of Germany and France marched east to restore Edessa, other Crusaders went to Spain to fight Muslims or to the shores of the Baltic Sea to fight the pagan Wends.

The situation in the East was also different. Manuel Comnenus, the Byzantine emperor, was not pleased to discover another Crusade headed toward Constantinople. The Second Crusade wreaked havoc with his foreign policy, which included an alliance with Germany, Venice, and the pope against the Normans. It also complicated the emperor's peaceful relationship with the Turkish sultan of Rūm. Manuel made a truce with the sultan in 1146 to make certain that the Crusade would not cause the sultan to attack Byzantine lands in Asia. Although sound strategically, the emperor's move confirmed for many Western Christians the apostasy of the Greeks.

Conditions in the East

Conrad left in May 1147, accompanied by many German nobles, the kings of Poland and Bohemia, and Frederick of Swabia, his nephew and the future emperor Frederick I (Frederick Barbarossa). Conrad's poorly disciplined troops created tension in Constantinople, where they arrived in September. Conrad and Manuel, however, remained on good terms, and both were apprehensive about the moves of King Roger II of Sicily, who, during these same weeks seized Corfu and attacked the Greek mainland.

Conrad, rejecting Manuel's advice to follow the coastal route around Asia Minor, moved his main force past Nicaea directly into Anatolia. On October 25, at Dorylaeum, not far from where the First Crusaders won their victory, his army, weary and without adequate provisions, was set upon by the Turks and virtually destroyed. Conrad, with a few survivors, retreated to Nicaea.

Louis VII, accompanied by his wife, Eleanor of Aquitaine, followed the land route across Europe and arrived at Constantinople on October 4, about a month after the Germans. A few of his more hotheaded followers, on hearing that Manuel had made a truce with the Turks of Iconium, accused the emperor of treason and urged the French king to join Roger in attacking the Byzantines. Louis preferred the opinion of his less volatile advisers and agreed to restore any imperial possessions he might capture.

In November, the French reached Nicaea, where they learned of Conrad's defeat. Louis and Conrad then started along the coastal route, with the French now in the vanguard, and reached Ephesus. Conrad became seriously ill and returned to Constantinople to the medical ministrations of Manuel. After recuperating, he eventually reached Acre by ship in April 1148.

The French passage from Ephesus to Antioch in midwinter was extremely harrowing. Supplies ran short, and the Byzantines were unjustly blamed. Manuel defended his cities against the angry Crusaders, which meant that the French spent more energy fighting Christians than Muslims. Louis concluded that the Greeks were trying to weaken the Crusade. He also had lost the bulk of his troops to Turkish attacks by the time he reached Antioch, which was ruled by Eleanor's uncle, Prince Raymond. The Crusade's original goal of recapturing Edessa was no longer feasible because Nūr al-Dīn, the son and successor of Zangī, had massacred the city's Christian inhabitants, making it difficult to take and hold Edessa with the forces available. Raymond urged an attack on Aleppo, Nūr al-Dīn's centre of power. But King Louis, who resented Eleanor's open espousal of Raymond's project, left abruptly for Jerusalem and forced the queen to join him.

In Jerusalem, where Conrad had already arrived, many French and German notables assembled with Queen

Melisende, her son Baldwin III, and the barons of Jerusalem to discuss how best to proceed. Despite the absence of the northern princes and the losses already suffered by the Crusaders, it was possible to field an army of nearly 50,000 men, the largest Crusader army so far assembled. After considerable debate, which revealed the conflicting purposes of Crusaders and Jerusalem barons, it was decided to attack Damascus.

Attack on Damascus

How the decision was reached is not known. Damascus was undoubtedly a tempting prize, but Unur, the Turkish commander, who was also fearful of the expanding power of Nūr al-Dīn and was the one Muslim ruler most disposed to cooperate with the Franks, was now forced to seek the aid of his former enemy. And Nūr al-Dīn was not slow to move toward Damascus. Not only was the Crusade campaign poorly conceived, it was badly executed. On July 28, after a four-day siege, with Nūr al-Dīn's forces nearing the city, it became evident that the Crusader army was dangerously exposed, and a retreat was ordered. It was a humiliating failure, attributable largely to the conflicting interests of the participants.

Conrad decamped for Constantinople, where he agreed to join the emperor against Roger of Sicily. Louis's reaction was different. His resentment against Manuel, whom he blamed for the failure, was so great that he accepted Roger's offer of ships to take him home and agreed to a plan for a new Crusade against Byzantium. Lacking papal support, the plan came to nothing, but the perception that the Byzantines were part of the problem rather than the solution became widespread in Europe.

The Second Crusade had been promoted with great zeal and had aroused high hopes. Its collapse caused deep dismay. Searching for an explanation, St. Bernard turned to Scripture and preached that the Crusade failed because of the sinfulness of Europe. Only through the purification and prayers of Christian men and women would God relent and bestow victory on his knights once more. This belief became central to Crusading ideology and an important impetus for movements of lay piety during the Middle Ages. The Muslims, on the other hand, were enormously encouraged by the collapse of the Second Crusade because they had confronted the danger of another major Western expedition and had triumphed.

The Crusader states to 1187. During the 25 years following the Second Crusade the Kingdom of Jerusalem was governed by two of its ablest rulers, Baldwin III (reigned 1143–62) and Amalric I (1163–74). In 1153 King Baldwin captured Ascalon, extending the kingdom's coastline southward, though this would be the Franks' last major conquest. Its possession was offset the next year by the occupation of Damascus by Nūr al-Dīn, one more stage in the encirclement of the Crusader states by a single Muslim power.

In 1160–61 the possibility that the Fāṭimid caliphate in Egypt, shaken by palace intrigues and assassinations, might collapse under the influence of Muslim Syria caused anxiety in Jerusalem. Thus, in 1164, when Nūr al-Dīn sent his lieutenant Shīrkūh to Egypt accompanied by his own nephew, Saladin, King Amalric decided to intervene. After some maneuvering, the armies of both Amalric and Shīrkūh withdrew, as they were to do again three years later.

Meanwhile, Amalric, realizing the necessity of Byzantine cooperation, had sent Archbishop William of Tyre as an envoy to Constantinople. In 1168, before the news of the agreement that William of Tyre had arranged reached Jerusalem, the king, for reasons unknown, set out for Egypt. The venture failed, and Shīrkūh entered Cairo. On his death (May 23, 1169), Saladin, then Nūr al-Dīn's deputy, was left to overcome the remaining opposition and assume control of Egypt.

The accession of Saladin

When the Byzantine fleet and the army finally arrived in 1169, there was some delay, and both armies were forced by inadequate provisions and seasonal rains to retreat once again, each side blaming the other for the lack of confrontation. In 1171, Saladin obeyed Nūr al-Dīn's order to have the prayers in the mosques mention the caliph of Baghdad instead of the caliph of Cairo, whose health was failing. Thus ended the Fāṭimid caliphate and the great division in Levantine Islām from which the Latins had profited.

Ominous developments followed the deaths of both Amalric and Nūr al-Dīn in 1174. In 1176 the Seljuqs of Iconium defeated the armies of Emperor Manuel Comnenus at Myriocephalon. It was a shattering blow reminiscent of Manzikert a century earlier. When Manuel died in 1180, all hope of effective Byzantine-Latin cooperation vanished. Three years later Saladin occupied Aleppo, virtually completing the encirclement of the Latin states. In 1185, he agreed to a truce and left for Egypt.

In Jerusalem, Amalric was succeeded by his son Baldwin IV, a 13-year-old boy suffering from leprosy. Despite the young king's extraordinary fortitude, his precarious health necessitated continuous regencies and created a problem of succession until his sister Sibyl bore a son, the future Baldwin V, to William of Montferrat. Her subsequent marriage in 1180 to Guy of Lusignan, a newcomer to the East and brother of Amalric, accentuated existing rivalries among the barons. A kind of "court party"—centring on the queen mother, Agnes of Courtenay, her daughter Sibyl, and Agnes's brother, Joscelin III of Edessa, and now including the Lusignans—was often opposed by another group comprising mostly the so-called native barons—old families, notably the Ibelins, Reginald of Sidon, and Raymond III of Tripoli, who through his wife was also lord of Tiberias. In addition to these internal problems, the kingdom was more isolated than ever. Urgent appeals to the West and the efforts of Pope Alexander III had brought little response.

Baldwin IV died in March 1185, leaving, according to previous agreement, Raymond of Tripoli as regent for the child king Baldwin V. But when Baldwin V died in 1186, the court party outmaneuvered the other barons and, disregarding succession arrangements that had been formally drawn up, hastily crowned Sibyl. She in turn crowned her husband, Guy of Lusignan.

In the midst of near civil war, Reginald of Châtillon, lord of Kerak and Montréal, broke the truce with the Muslims by attacking a caravan. Saladin replied by proclaiming

jihad against the Latin kingdom. In 1187 he left Egypt, crossed the Jordan south of the Sea of Galilee, and took up a position close to the river. Near Sepphoris (modern Zippori) the Crusaders mobilized an army of perhaps 20,000 men, which included some 1,200 heavily armed cavalry. In a spot well chosen and adequately supplied with water and provisions, they waited for Saladin—who, by some estimates, had about 30,000 men, half of whom were light cavalry—to make the first move.

On July 2, Saladin blocked the main road to Tiberias and sent a small force to attack the town, hoping that Count Raymond's wife's presence there would lure the Crusaders into the open. It was Raymond, however, who initially persuaded the king not to fall into the trap. But, late that night, others, accusing the count of treason, prevailed upon the king to change his mind. This fateful decision would lead to the destruction of the Crusader army. On July 3, the Crusaders undertook an exhausting day's march, spent a terrible night without water, and were surrounded and constantly harassed. The following day they faced Saladin's forces at the Horns of Ḥaṭṭīn and fought throughout the day with smoke from grass fires set by the enemy pouring into their faces. When the infantry broke ranks, the essential coordination with the cavalry was shattered, and the Crusaders' fate was sealed. By the time Saladin's final charge ended the battle, most of the knights had been slain or captured. Only Raymond of Tripoli, Reginald of Sidon, Balian of Ibelin, and a few others escaped.

Battle of Ḥaṭṭīn

The king's life was spared, but Saladin killed Reginald of Châtillon and ordered the execution of some 200 Templars and Hospitallers (religio-military orders discussed below). Other captive knights were treated honourably, and most were later ransomed. Less fortunate were the foot soldiers, most of whom were sold into slavery. Virtually the entire military force of the Kingdom of Jerusalem had been destroyed. To make matters worse, Saladin captured the relic of the True Cross, which he sent to Damascus, where it was paraded through the streets upside down.

Saladin quickly followed up his victory in the Battle of Ḥaṭṭīn by taking Tiberias and moving toward the coast to seize Acre. By September 1187 he and his lieutenants had occupied most of the major strongholds in the kingdom and all of the ports south of Tripoli, except Jubayl and Botron (al-Batrūn) in the County of Tripoli and Tyre in the kingdom. On October 2 Jerusalem, then defended by only a handful of men under the command of Balian of Ibelin, capitulated to Saladin, who agreed to allow the inhabitants to leave once they paid a ransom. Though Saladin's offer included the poor, several thousand apparently were not redeemed and probably were sold into slavery. In Jerusalem, as in most of the cities captured, those who stayed were Syrian or Greek Christians. Somewhat later Saladin permitted a number of Jews to settle in the city.

Meanwhile, Saladin continued his conquests in the north, and by 1189 all the kingdom was in his hands except Belvoir (modern Kokhov ha-Yarden) and Tyre. The County of Tripoli and the Principality of Antioch were each reduced to the capital city and a few outposts. The majority of the 100-year-old Latin establishment in the Levant had been lost.

The institutions of the First Kingdom. The four principalities established by the Crusaders—three after the loss of Edessa in 1144—were loosely connected, and the king of Jerusalem's limited suzerainty over Antioch and Tripoli became largely nominal after midcentury. Each state was organized into a pattern of lordships by the ruling Christian minority. The institutions of the Kingdom of Jerusalem are known best, partly because its history figures more prominently in both Arab and Christian chronicles but especially because its documents were better preserved.

Law code

In the 13th century, the famous legal compilation the *Assises de Jérusalem* was prepared in the kingdom. Though this collection reflects a later situation, certain sections and many individual enactments can be traced back to the 12th century, the period known as the First Kingdom.

In the first half of the 12th century, the kingdom presented the appearance of a typical European monarchy, with lordships owing military service and subject to fiscal exactions. There were, however, important differences, not only in the large subject population of diverse ethnic origins but also with respect to the governing minority. No great families with extensive domains emerged in the early years, and the typical noble did not, as in Europe, live in a rural castle or manor house. Although castles existed, they were garrisoned by knights and, increasingly as the century advanced, by the religio-military orders. Most barons in the kingdom lived in the fortified towns. The kings, moreover, possessed a considerable domain and retained extensive judicial rights, which made the monarchy a relatively strong institution in early Jerusalem.

Toward the middle of the century this situation changed. Partly as a consequence of increased immigration from the West, the baronial class grew, and a relatively small group of magnates with large domains emerged. As individuals, they were less disposed to brook royal interference, and as a class and in the court of barons (*Haute Cour*, or High Court) they were capable of presenting a formidable challenge to royal authority. The last of the kings of Jerusalem to exercise effective power was Amalric I in the 12th century. In the final years of the First Kingdom, baronial influence was increasingly evident and dissension among the barons, as a consequence, more serious.

The military orders. Another serious obstacle to the king's jurisdiction, which did not exist in the same form in the West, was the extensive authority of two religio-military orders. The Knights of the Hospital of St. John, or Hospitallers, was founded in the 11th century by the merchants of Amalfi to provide hospital care for pilgrims. The order never abandoned its original purpose, and, in fact, as its superb collection of documents reveals, the order's philanthropic activities expanded. But during the 12th century, in response to the military needs of the kingdom, the Hospitallers also became an order of knights, as did the Poor Knights of Christ and of the Temple of Solomon, so named because of its headquarters in the former temple of Solomon. The Templars originated as a monastic-military organization dedicated to protecting pilgrims on the way to Jerusalem, and its rule, composed by St. Bernard of Clairvaux, was officially sanctioned by the Council of Troyes (1128). Although the Templars and Hospitallers took monastic vows, their principal function was soldiering.

Hospitallers and Templars

The orders grew rapidly and acquired castles at strategic points in the kingdom and in the northern states. They maintained permanent garrisons in these castles and supplemented the otherwise inadequate forces of the barons and king. Moreover, because they were soon established in Europe as well, they became international organizations. Virtually independent, sanctioned and constantly supported by the papacy, and exempt from local ecclesiastical jurisdiction, they aroused the jealousy of the clergy and constituted a serious challenge to royal authority.

The Crusaders introduced into the conquered lands a Latin ecclesiastical organization and hierarchy. The Greek patriarch of Antioch was removed, and all subsequent incumbents were Latin, except for one brief period before 1170 when imperial pressure brought about the installation of a Greek. The Orthodox patriarch in Jerusalem left before the conquest and died soon after. All his successors were Latin.

Under Latin jurisdiction were the entire Latin population and those natives (Greeks in Antioch and Greeks or native Syrians [Melchites] in Jerusalem) who had remained Orthodox. Beyond that jurisdiction was a larger number of Monophysites (Jacobites or Armenians) and some few Nestorians, all adherents of doctrines that had deviated from the decisions of 5th-century ecumenical councils. A number of Maronites of the Lebanon region accepted the Latin obedience late in the 12th century. After some initial confusion, the native hierarchies were able to resume their functions.

As in the West, the church had its own courts and possessed large properties. But each ecclesiastical domain was required to furnish soldiers, and there were considerable charitable foundations. The hierarchy of the Latin states was an integral part of the church of the West. Papal legates regularly visited the East, and bishops from the Crusader states attended the Third Lateran Council in

1179. Western monastic orders also appeared in the Crusader states.

In addition to the nobles and their families who had settled in the kingdom, a substantially larger number of persons were classified as bourgeois. A small number had arrived with the First Crusade; however, most were later immigrants from Europe, predominantly from rural southern France but representing nearly every nationality. In the East they became town dwellers, though a few were agriculturalists—proprietors of small estates, rarely themselves tillers of the soil, inhabiting the more modest towns. It appears some immigrants, perhaps poor pilgrims who remained, failed to obtain a reasonably settled status and could not afford the relatively small ransom offered by Saladin in 1187.

The bourgeois

The townspeople of the First Kingdom did not, like their counterparts in Europe, aspire to political autonomy. There were no communal movements in the 12th century. The bourgeois were, therefore, subject to a king or seigneur. Some did military service as sergeants—*i.e.*, mounted auxiliaries or foot soldiers. The bourgeois were recognized as a class in the more than 30 "courts of the bourgeois" according to procedures laid down in the *Assises de la cour des bourgeois*, which, unlike other parts of the *Assises*, reflect the traditions of Roman law in southern France.

The Italians had acquired exceptional privileges in the ports because they supplied the indispensable naval aid and shipping essential to regular contact with Europe. These privileges usually included a quarter that they maintained as a virtually independent enclave. Its status was guaranteed by treaty between the kingdom and the "mother" city (Venice, Genoa, Pisa, etc.).

European settlers in the Crusader states, however, were only a small minority of the population. If the early Crusaders were ruthless, their successors, except for occasional outbursts during campaigns, were remarkably tolerant and flexible in dealing with the diverse sectors of the native population. Muslim town dwellers who had not fled were captured and put to menial tasks. Some, it is true, appeared in Italian slave marts, but royal and ecclesiastical ordinances at least restricted slave owners' actions. Baptism brought with it immediate freedom.

Few Muslims were slaves. Most of those who remained were peasants who for centuries had been a large part of the rural population and were permitted to retain their holdings, subject to fiscal impositions not unlike those of the European serf and usually identical to those originally levied by their former proprietors on all non-Muslims. Muslim nomads, or Bedouins, who from time immemorial had moved their herds with the seasons, were granted their traditional rights of pasturage by the king.

Most mosques were appropriated during the conquest, but some were restored, and no attempt was made to restrict Muslim religious observance. Occasionally a mihrab (prayer niche) was retained for Muslim worshippers in a church that had formerly been a mosque. The tolerance of the Franks, noted by Arab visitors, often surprised and disturbed newcomers from the West.

Legal practices. Native Christians were governed according to the *Assises de la cour des bourgeois*. Each national group retained its institutions. The Syrians, for example, maintained a court overseen by the *rais* (*ra'īs*), a chieftain of importance under the Frankish regime. An important element in the kingdom's army, the corps of Turcopoles, made up of lightly armed cavalry units, was also composed largely of native Christians, including, apparently, converts from Islām. The principle of personality of law applied to all: the Jew took oath on the Torah, the Samaritan on the Pentateuch, the Muslim on the Qur'ān, and the Christian on the Gospels.

The Jewish community of Palestine, which had declined in the 11th century, was drastically reduced by the First Crusade. As the Latin kingdom settled into a routine of government, however, the situation improved. Indeed, there is reason to believe that the later, more stable regime made possible a not inconsiderable Jewish immigration, not, it seems, as in earlier times, from the neighbouring lands of the Middle East, but from Europe.

Thus, by the 1170s the Crusader states of Outremer, as the area of Latin settlement came to be called, had developed well-established governments. With allowance made for regional differences (*e.g.*, Antioch in its early years under the Norman dynasty was somewhat more centralized), the institutions of the northern states resembled those of Jerusalem. The governing class of Franks was no longer made up of foreign conquerors but of local residents who had learned to adjust to a new environment and were concerned with administration. A few—such as Reginald of Sidon and William of Tyre, the archbishop and chancellor, respectively—were fluent in Arabic. Many others knew enough of the language to deal with the local inhabitants. Franks adopted native dress, ate native food, employed native physicians, and married Syrian, Armenian, or converted Muslim women.

But the Franks of Outremer, though they sometimes acquired a love of luxury and comfort, did not lose the will or ability to confront danger; nor did they "go native." In fundamentals, they were Latin Christians who adhered to the traditions of their French forebears. The *Assises* were in French, and other documents were drawn up in Latin. William of Tyre, born in the East but educated in Europe, wrote a celebrated *History of Deeds Done Beyond the Sea* in the Latin style of the 12th century.

The Franks' cultural identity

Artists and architects were influenced by Byzantine and Arab craftsmen, but Oriental motifs were usually limited to details, such as doorway carvings. A psalter for Queen Melisende in the 12th century, for example, shows certain Byzantine characteristics, and the artist may have lived in Constantinople, but the manuscript is in the then-current tradition of French art. Castles followed Byzantine models and were often built on the old foundations, though Western ideas were also incorporated. New churches were built or additions made to existing structures, as for example the Church of the Holy Sepulchre, in the Romanesque style of the homeland.

All in all, the Franks of the First Kingdom developed a distinctive culture and achieved a sense of identity. Until baronial dissensions weakened the monarchy in later years, the Latin kingdom showed remarkable vitality and ingenuity. It was one of the more sophisticated governmental achievements of the Middle Ages.

The Third Crusade. The news of the fall of Jerusalem reached Europe even before the arrival there of Archbishop Josius of Tyre, whom the Crusaders had sent with urgent appeals for aid. Pope Urban III soon died, shocked, it was said, by the sad news. His successor, Gregory VIII, issued a Crusade bull and called for fasting and penitence.

Before a new Crusade could be organized, however, a modest recovery had begun in the East. Scarcely two weeks after Ḥaṭṭīn, Conrad of Montferrat, Baldwin V's uncle, had landed at Tyre with a small Italian fleet and a number of followers. He immediately established himself sufficiently to stave off an attack by Saladin. Conrad also refused to submit to King Guy when Saladin released the king at the end of 1188 as promised.

In a daring move to reestablish his authority, Guy suddenly gathered his few followers and besieged Acre, taking Saladin completely by surprise. When the Muslim leader finally moved his army toward the city, the Crusaders, camped outside, had begun to receive reinforcements from the West, many under the banner of Henry of Champagne. By the winter of 1190–91 neither side had made progress; Saladin could not relieve the city, but the Crusaders had suffered losses from disease and famine.

Among the victims of disease was Guy's wife, Sibyl, the source of his claims to the throne. Many of the older barons who had thus far supported him now turned to Conrad. The marriage of Sibyl's sister, Isabel, to Humphrey of Toron was forthwith annulled, and she was constrained to marry Conrad. But Guy refused to abandon his claim to the throne. Such was the situation in May 1191, when ships arrived off Acre bringing welcome supplies and news of the approach of the armies of the Third Crusade.

The first ruler to respond to the papal appeal was William II of Sicily, who immediately abandoned a conflict with Byzantium and equipped a fleet that soon left for the East, though William himself died in November 1189. English,

The siege of Acre, 1191, from "Chroniques de France ou de St. Denis," *c.* 1375–*c.* 1400.

The Holy Roman emperor takes the cross

Danish, and Flemish ships also departed. Meanwhile, Gregory VIII had sent a legation to the Holy Roman emperor and participant in the Second Crusade, Frederick Barbarossa, now nearly 70 years old and approaching the end of an eventful career. Although excommunicated by Pope Alexander III and a supporter of antipopes in the 1160s and 1170s, Frederick had made peace with the church in 1177 and for some time had been genuinely desirous of going on Crusade again.

He set out in May 1189 with the largest Crusader army so far assembled and crossed Hungary into Byzantine territory. The Byzantine emperor, Isaac II Angelus, had made a secret treaty with Saladin to impede Frederick's progress through Greece, which he did quite effectively. Frederick responded by capturing the Byzantine city of Adrianople, returning it only when Isaac agreed to transport the Germans across the Hellespont into Turkey. In May 1190 Frederick reached Iconium after defeating a Seljuq army. His forces then crossed into Armenian territory. On June 10 Frederick, who had ridden ahead with his bodyguard, was drowned while attempting to swim a stream. His death broke the morale of the German army, and only a small remnant, under Frederick of Swabia and Leopold of Austria, finally reached Tyre. To Saladin and the Muslims, who had been seriously alarmed by Frederick's approach, the emperor's death seemed an act of God.

In Europe, Archbishop Josius had won over Philip II Augustus of France and Henry II of England, whose son and successor (Richard I the Lion-Heart), took up the cause when Henry died in 1189. The extensive holdings of the English Angevin kings in France and especially Philip's desire to recover Normandy, however, posed problems that were difficult to lay aside even during a common enterprise. Thus, it was not until July 4, 1190, three years after Ḥaṭṭīn, that the English and French rulers met at Vézelay and prepared to move with their armies.

The two kings who finally led the Third Crusade were very different persons. Richard had opposed his father and was distrustful of his brothers. He could be lavishly generous even to his adversaries but often violent to anyone who stood in his way. His abilities lay not in administration, for which he had no talent, but in war, at which he was a genius. The favourite son of Eleanor of Aquitaine, Richard epitomized the chivalrous Crusader and personified the contemporary troubadour's view of war with all its aristocratic *courtoisie*. Richard could honour his noble Muslim opponents but be utterly ruthless to lowborn captives.

The role of Richard I and Philip II

Unlike Richard, Philip II had been king for 10 years and was a skilled and unscrupulous politician. He had no love for ostentation. Though no warrior himself, he was adept at planning sieges and designing siege engines. But he was a reluctant Crusader whose real interests lay in the expansion of his own domains.

At the suggestion of King William II, Richard and Philip met at Messina, in Sicily, where they signed an agreement outlining their mutual obligations and rights on the Crusade. Philip arrived with the French fleet at Acre on April 20, 1191, and the siege was begun again in earnest.

After a stormy passage, Richard put in at Cyprus, where his sister Joan and his fiancée, Berengaria of Navarre, had been shipwrecked and held by the island's Byzantine ruler, a rebel prince, Isaac Comnenus. Isaac underestimated Richard's strength and attacked. Not only did Richard defeat and capture him, but he proceeded to conquer Cyprus, an important event in the history of the Crusades. The island would remain under direct Latin rule for the next four centuries and would be a vital source of supplies throughout the Third Crusade and beyond. Even after the fall of the Crusader states, Cyprus remained a Christian outpost in the East.

Richard left Cyprus and arrived on June 8 at Acre, where he reinvigorated the siege. A month later, after constant battering at the walls by siege engines and after Saladin's nephew had failed to fight his way into the city, the garrison surrendered in violation of Saladin's orders. The Muslim leader was shocked by the news, but nevertheless he ratified the surrender agreement. In exchange for the lives of the Muslim garrison, he agreed to return the True Cross, render 200,000 dinars, and release all of his Christian prisoners—still more than 1,000 men.

As the Crusaders entered the city, disputes arose over the disposal of areas. Richard offended Leopold of Austria, and Philip, who felt that he had fulfilled his Crusader's vow and who was unwell, left for home in August. Though the

English and French troops resented Philip's departure, it did leave Richard in control. When Saladin failed to pay the first installment of the ransom for the prisoners on schedule, Richard flew into a rage. He ordered that all 2,700 members of the Muslim garrison be marched outside the city and executed in view of Saladin and his army. Saladin responded by massacring most of his Christian hostages. Clearly, the deal was off.

The first and only pitched battle between the forces of Saladin and the Third Crusade occurred on September 7, 1191, at Arsuf. Richard's military brilliance won the day, forcing Saladin to retreat with heavy losses, while the English king's casualties were very light. After Arsuf, Saladin decided not to risk open battle again with Richard, who quickly recaptured Jaffa and established it as his base of operations. Richard next reestablished Christian control of the coast and refortified Ascalon to the south. Twice Richard led the Crusaders to Jerusalem, yet on both occasions he was forced to retreat after coming within sight of the Holy City. Without control of the hinterland, the king knew that he could not hold Jerusalem for long. Although tactically sound, Richard's refusal to lay siege to the city was bitterly unpopular among the rank and file. As a result, his suggestion that the Crusade attack Saladin's power base in Egypt was rejected by most of the Crusaders.

After Philip returned to France, he preyed upon Richard's lands; though forbidden by the church, these actions were lucrative nonetheless. Richard received urgent messages from home requesting his return. Meanwhile, he had been in constant communication with Saladin and his brother al-ʿĀdil, and various peace proposals were made, which included marriage alliances. In fact, there seemed to be warm cordiality and considerable mutual respect between Richard and Saladin. Finally, on September 2, 1192, the two signed a three-year peace treaty. The coast from Jaffa north remained in Christian hands, but Ascalon was to be restored to Saladin after Richard's men demolished the fortifications that they had painstakingly built. Pilgrims were to have free access to the holy places. On October 9 Richard left. He was shipwrecked and finally fell into the hands of Leopold of Austria, who had not forgotten the slight at Acre.

Assessment of the Third Crusade

The Third Crusade had failed to attain its main objective, the retaking of Jerusalem, but in every other way it was a great success. Most of Saladin's victories in the wake of Ḥaṭṭīn were wiped away. Before he left, Richard consented to the request that Guy, who had lost the support of nearly all the barons, be deposed and Conrad immediately be accepted as king. No sooner was this done than Conrad was assassinated. Isabel was persuaded to marry Henry of Champagne, and Guy was given the governorship of Cyprus, where his record was far more successful than his ill-starred career in Jerusalem. Although he had failed to recapture Jerusalem, Richard had put the Christians of the Levant back on their feet.

The Latin East after the Third Crusade. Saladin died on March 3, 1193, not long after the departure of the Third Crusade. One of the greatest Muslim leaders, a man devoutly religious and deeply committed to jihad against the infidel, he was, nevertheless, respected by his opponents. His death led once again to divisions in the Muslim world, and his Ayyūbid successors were willing to continue a state of truce with the Crusaders, which lasted into the early years of the 13th century. The truce was politically and economically advantageous for both sides, and the Italians were quick to make profitable trade connections in Egypt. The Franks were able to adjust to the new situation and to organize what in effect was a new titular kingdom of Jerusalem centring on Acre, generally known as the Second Kingdom.

In 1194 Amalric of Lusignan succeeded his brother Guy as ruler of Cyprus, where he later accepted investiture as king from the chancellor of Emperor Henry VI. In 1197, following the death of Henry of Champagne, Amalric succeeded to the throne of Jerusalem, and in 1198 he married the thrice-widowed Isabel. He chose, however, to govern his two domains separately, and in Acre he proved to be an excellent administrator. The *Livre au roi* ("Book of the King"), an important section of the *Assises de Jérusalem*, dates from his reign. He also dealt wisely with Saladin's brother, al-ʿĀdil of Egypt. On Amalric's death in 1205, the kingdoms of Cyprus and Jerusalem were divided, and in 1210 the latter was given to John of Brienne, a French knight nominated by Philip, who came east and married Conrad's daughter, Mary.

There were also adjustments in the two northern states. When Raymond III of Tripoli died (1187), his county passed to a son of Bohemond III of Antioch, thus uniting the two principalities. In general, Antioch-Tripoli followed the relatively independent course laid down by Bohemond III.

Armenia was more closely involved in Latin politics, partly as a result of marriage alliances with the house of Antioch-Tripoli. King Leo II of Armenia joined the Crusaders at Cyprus and Acre. Desirous of a royal crown, he approached both pope and emperor, and in 1198, with papal approval, royal insignia were bestowed by Archbishop Conrad of Mainz, in the name of Henry VI. At the same time, the Armenian church officially accepted a union with Rome, which, however, was never popular with the lower clergy and general populace.

THE FOURTH CRUSADE AND THE LATIN EMPIRE OF CONSTANTINOPLE

Pope Innocent III was the first pope since Urban II to be both anxious and able to make the Crusade a major papal concern. In 1198 he called a new Crusade through legates and encyclical letters. In 1199 a tax was levied on all clerical incomes—later to become a precedent for systematic papal income taxes—and Fulk of Neuilly, a popular orator, was commissioned to preach. At a tournament held by Thibaut III of Champagne, several prominent French nobles took the cross. Among them was Geoffrey of Villehardouin, author of one of the principal accounts of the Crusade; other important nobles joined later, and contact was made with Venice to provide transport.

Unfortunately, Thibaut of Champagne died before the Crusaders departed for Venice, and the barons turned to Boniface of Montferrat, whose involvement as leader of the Crusade proved to be fateful. He had close family ties with both the Byzantine Empire and the Crusader states. His brother, Conrad of Montferrat, had received the crown of Jerusalem only to be murdered by the Assassins (an Islāmic extremist sect) shortly thereafter. Before coming to the Holy Land, Conrad had married the sister of Emperor Isaac II Angelus and received the title of Caesar. Boniface was also the vassal of Philip of Swabia, who was a contender for the German throne and the son-in-law of Isaac II. In 1195, Isaac was blinded and deposed by his brother, who took the throne as Alexius III. Several years later, Isaac's son, also named Alexius, escaped from Constantinople and fled to Philip's court. At Christmas 1201, Boniface, Philip, and the young Alexius discussed the possibility of using the Crusade to depose Alexius III and place the young man on the throne. Boniface sought the approval of the pope for the diversion, but Innocent refused to allow it. The young Alexius also journeyed to Rome, but had no better luck with Innocent III. Despite the papal prohibition, Boniface and the Byzantine prince still hoped to find a way to move the Crusade toward Constantinople on its way to the Holy Land.

Byzantine politics

When the Crusader army arrived in Venice in the summer of 1202 it was only one-third of its projected size. This was a serious problem, since the French had contracted with the Venetians for a fleet and provisions that they now realized they neither needed nor could afford. The Venetians had incurred enormous expense for the French and were understandably upset by their inability to pay. The leader of Venice, Doge Enrico Dandolo, was a man of great sagacity and prudence who was in his nineties and completely blind by the time of the Crusade. Dandolo proposed that if the French would assist the Venetians in capturing the rebellious city of Zadar (now in Croatia), he would be willing to suspend the outstanding debt until it could be paid in captured booty. With few options, the Crusaders agreed, even though Zadar was a Christian city under the control of the king of Hungary, who had taken the Crusader's vow. Innocent was informed of the plan,

but his veto was disregarded. In November 1202, the Crusaders captured Zadar and wintered there. Reluctant to jeopardize the Crusade, Innocent gave conditional absolution to the Crusaders, but not to the Venetians.

Meanwhile, envoys from Philip of Swabia arrived at Zadar with an offer from Alexius, the Byzantine prince. If the Crusaders would sail to Constantinople and topple the reigning emperor, Alexius would place the Byzantine church in submission to Rome, pay the Crusaders an enormous sum, and join the Crusade to Egypt (now the centre of Muslim power in the Levant) with a large army. It was a tempting offer for an enterprise that was short on funds. The Crusade leaders accepted it, but a great many of the rank and file wanted nothing to do with the proposal and many deserted. The Crusade sailed to Corfu before arriving in Constantinople in late June 1203. After the Crusaders attacked the northeastern corner of the city and set a destructive fire, the citizens of Constantinople turned against Alexius III, who then fled. The Byzantine prince was elevated to the throne as Alexius IV along with his blind father, Isaac II.

Although the new emperor tried to make good his promises to the Crusaders, he soon ran short of money. He also faced anti-Latin hatred in Constantinople, which had been endemic for decades and now reached a fever pitch. Alexius IV, who owed his throne to Latins, became bitterly unpopular and was finally toppled in a palace coup in late January 1204. The Crusaders, now cheated of their reward and disgusted at the treachery of the Byzantines, declared war on Constantinople, which fell to the Fourth Crusade on April 12, 1204. What followed was one of the most profitable and disgraceful sacks of a city in history. Despite their oaths and the threat of excommunication, the Crusaders ruthlessly and systematically violated the city's holy sanctuaries, destroying, defiling, or stealing all they could lay hands on. Many also broke their vows to respect the women of Constantinople and assaulted them. When Innocent III heard of the conduct of his pilgrims, he was filled with shame and strongly rebuked them.

Sack of Constantinople

Before the capture of Constantinople, the Crusaders had decided that 12 electors (six Venetians and six Franks) should choose an emperor who would rule one-fourth of the imperial domain. The other three-fourths were to be divided. The clergy of the party that did not include the emperor elect were to oversee Hagia Sophia and choose a patriarch. A small amount of property was specifically designated to support the clergy, and the rest was divided as booty.

Once order had been restored, the Franks and the Venetians implemented their agreement; Baldwin of Flanders was elected emperor, and the Venetian Thomas Morosini chosen patriarch. Various Latin-French lordships throughout Greece—in particular, the duchy of Athens and the principality of the Morea—did provide cultural contacts with western Europe and promoted the study of Greek. There was also a French impact on Greece. Notably, a collection of laws, the *Assises de Romanie*, was produced. The *Chronicle of the Morea* appeared in both French and Greek (and later Aragonese) versions. Impressive remains of Crusader castles and Gothic churches can still be seen in Greece. Nevertheless, the Latin empire always rested on shaky foundations. Indeed, not all of the Byzantine Empire was conquered by the Crusade. The imperial government continued in Nicaea, and the offshoot Empire of Trebizond, at the eastern end of the Black Sea, lasted until 1461. The Byzantine Despotate of Epirus was also established, and the Bulgarians remained hostile to the Crusaders. Finally, in 1261 a sadly diminished Constantinople was reconquered by Michael VIII Palaeologus with the aid of Genoa, the traditional rival of Venice. The city, however, would never be the same. For the remainder of its Christian history, it would remain poor, dilapidated, and largely abandoned.

The belief that the conquest of Constantinople would help Crusading efforts was a mirage. Indeed, the opposite was true, for the unstable Latin Empire siphoned off much of Europe's Crusading energy. The legacy of the Fourth Crusade was the deep sense of betrayal the Latins had instilled in their Greek coreligionists. With the events of 1204, the schism between the Catholic West and Orthodox East was complete.

Crusades of the 13th century

CRUSADES IN THE WEST

The Albigensian Crusade. By the mid-12th century, control of Jerusalem and the Holy Land was no longer the only goal of the Crusade. Rather, it became a special class of war called by the pope against the enemies of the faith, who were by no means confined to the Levant. Crusades continued in the Baltic region against pagans and in Spain against Muslims. Yet in the heart of Europe a more serious threat faced Christendom—heresy. In the medieval world, heresy did not represent benign religious diversity but was seen as a cancerous threat to the salvation of souls. It was held to be even more dangerous than the faraway Muslims because it harmed the body of Christ from within.

The most vibrant heresy in Europe was Catharism, also known as Albigensianism for Albi, a city in southern France where it flourished. A dualist belief, Catharism held that the universe was a battleground between good, which was spirit, and evil, which was matter. Human beings were believed to be spirits trapped in physical bodies. The leaders of the religion, the perfects, lived with great austerity, remaining chaste and avoiding all foods that came from sexual union, including meat, cheese, and eggs.

Catharism

The church had attempted for years to root the heresy out of southern France, where it remained popular, particularly among the nobility. St. Dominic, who was sent to the region to preach to the people and debate the Cathar leaders, formed his Order of Preachers (Dominicans) in response to the heresy. All efforts at eradication failed, however, largely because of the tolerance of the Cathari maintained by Raymond VI of Toulouse, the greatest baron of the area, and by most secular lords in the region. Shortly after his excommunication for abetting the heretics, Raymond was implicated in the murder of a papal legate sent to investigate the situation. For Pope Innocent III, that was the final straw. In March 1208, he called for a Crusade against Raymond and the heretics of Languedoc, which began the following year.

The Albigensian Crusade was immensely popular in northern France because it gave pious warriors an opportunity to win a Crusade indulgence without traveling far from home or serving more than 40 days. During the first season, the Crusaders captured Béziers in the heart of Cathar territory and—following the instructions of the papal legate who allegedly said, "Kill them all. God will know his own," when asked how the Crusaders should distinguish the heretics from true Christians—massacred almost the entire population of the city. With the exception of Carcassonne, which held out for a few months, much of the territory of the Albigeois surrendered to the Crusaders. Command of the Crusade was then given to Simon, the lord of Montfort and earl of Leicester, who had served during the Fourth Crusade. Abandoning the Crusade after it attacked the Christians at Zadar, Simon had fought in the Holy Land.

Massacre at Béziers

The Albigensian Crusade dragged on for several years, with new recruits arriving each spring to assist Simon. By the end of the summer, however, they would all return home, leaving him with a skeleton force to defend his gains. By 1215, when the Fourth Lateran Council met to consider the state of the church, Simon had captured most of the region, including Toulouse. The council gave the lands to Simon and then rescinded the Crusade indulgence for the war so that a new Crusade to the East could be organized.

A few years later a rebellion against the northerners that crystallized around Raymond and his son, Raymond VII, recaptured much lost territory. Simon was killed during a siege of Toulouse. The Albigensian Crusade was finally brought to a close by the French King Louis VIII. Although he died soon after his victory in the south, Louis restored northern control over the region in 1226 and dashed the hopes of Raymond's family for an independent Toulouse. In 1229, the younger Raymond accepted a peace through which all of his ancestral lands would go to

the royal house of the Capetians at his death. It was, therefore, the French crown, which came to the Crusade quite late, that was the ultimate victor.

For all of its violence and destruction, the Albigensian Crusade failed to remove the Cathar heresy from Languedoc. It did, however, provide a solid framework of new secular lords willing to work with the church against the heretics. Through the subsequent efforts of the Dominican inquisitors, Catharism was virtually eliminated in Languedoc within a century.

The Children's Crusade. The same strong feelings of piety and righteousness that led knights to take the cross and march to war also affected the common people, who lacked the wealth or training to do the same. The repeated failure of the organized Crusades to reclaim Jerusalem and the True Cross frustrated all Christians. This combination of frustration and strong religious enthusiasm led to frequent and sometimes bizarre manifestations of popular piety, such as the so-called Children's Crusade in 1212.

The Children's Crusade was neither a Crusade, nor was it made up of an army of children. The pope did not call it—indeed, no one did. Instead, it was an unsanctioned popular movement, whose beginning and ending are hard to trace. It is known, however, that in early 1212 a young man named Nicholas of Cologne became the focal point for a popular movement that swept through the Rhineland. After allegedly receiving divine instruction, Nicholas set out to rescue Jerusalem from the Muslims. He believed that when he reached the Mediterranean, God would dry up the waters so that he could walk across to Palestine. Hundreds and then thousands of children, adolescents, women, the elderly, the poor, parish clergy, and the occasional thief joined him in his march south. In every town the people hailed the "Crusaders" as heroes, although the educated clergy ridiculed them as deranged or deceived. In July 1212, despite the summer heat that had caused many to give up and return home, Nicholas and his followers crossed the Alps into Italy.

Nicholas of Cologne

Word of Nicholas's Crusade spread across Europe, sparking similar "miracles" and popular movements, although usually on a much smaller scale. One such movement, which may actually have preceded the Rhineland Crusade, occurred in Cloyes, a small town in France, where Stephen, a 12-year-old shepherd, had a vision of Jesus, who appeared dressed as a pilgrim and asked for bread. After receiving some bread from the boy, Jesus gave him a letter for the king of France. Stephen then left for Paris and attracted hundreds of followers from the same constituency that Nicholas of Cologne did. As they marched toward Paris, they sang, "Lord God, exalt Christianity! Lord God, restore to us the True Cross!" When they reached the city, Stephen delivered the letter to Philip Augustus. The king thanked the boy for the letter, then everyone cheered and went home. The letter's contents are not known with certainty, but it was probably an exhortation for the king to once again Crusade—something Philip had no intention of doing.

By late summer Nicholas's multitudes had reached Lombardy and entered various port cities. Nicholas himself arrived with a large gathering at Genoa on August 25. To the great disappointment of the "Crusaders " the sea did not open for them, nor did it allow them to walk across its waves. At this point many probably returned home, while others remained in Genoa. It was said that some marched to Rome, where Innocent III praised their zeal but released them from their "vows." The fate of Nicholas is also unclear. Some claimed that he joined the Fifth Crusade, others that he died in Italy.

The Teutonic Knights and the Baltic Crusades. Founded during the Third Crusade, the Teutonic Knights were a German military order modeled on the Hospitallers. By the 13th century the order began to shift its focus from the Holy Land to Europe. From 1211 to 1225, it waged war against pagans in Transylvania and effectively Christianized the region but was subsequently expelled by the king of Hungary. The grand master of the order, Hermann von Salza, then agreed to assist the Polish duke Conrad of Mazovia in his war against the pagan Prussians of the Baltic region. The emperor and pope agreed that the Teutonic Knights should rule all pagan lands that they conquered, and during the 13th and 14th centuries the order conquered all of Prussia and the northern Baltic region, building a prosperous Christian state there. As rulers, the Teutonic Knights played an important part in European history for many centuries.

CRUSADES TO THE EAST

The Fifth Crusade. The Children's Crusade revealed that despite repeated failures, Europeans were still committed to recapturing Jerusalem and rescuing the True Cross. Almost immediately after the Fourth Crusade, Innocent III began planning for another expedition to the East. Although delayed by controversies involving the imperial succession and related matters, Innocent was ready to call the warriors of Christendom to fight for the restoration of Western rule in the Holy Land by 1213. Innocent learned from the mistakes of the Fourth Crusade and was determined that the new effort would be controlled every step of the way by the church. He commissioned a new corps of Crusade preachers, who were specially trained and then dispatched strategically to garner warriors. Innocent also sent out legates to oversee recruitment and preparations. He wanted this new Crusade to be an inclusive effort. Those who could not physically march to the East were enjoined to help the Crusade through prayer and fasting. Those with sufficient funds could share in the Crusade indulgence by financing a Crusader who would otherwise be unable to go. At the Fourth Lateran Council in 1215 the blueprints for the new campaign were drafted and all of Europe was directed to take part. Innocent, however, died before the first Crusaders left, and his successor, Honorius III, would oversee the progress of the Fifth Crusade.

Lessons of the Fourth Crusade

The first contingents of the Fifth Crusade, led by King Andrew of Hungary, reached Acre in the fall of 1217. Andrew accomplished little, however, before departing in January 1218. A large fleet of Frisian, German, and Italian Crusaders arrived in April and joined the remnants of Andrew's force. In May, the combined army set out for Egypt under the leadership of John of Brienne (the titular king of Jerusalem from 1210). The idea of capturing Egypt in order to break Muslim power in the region before turning to Jerusalem had been endorsed by Richard the Lion-Heart during the Third Crusade. Although controversial at the time, by the time of the Fifth Crusade it was the accepted strategy among Crusade leaders. By August the Crusaders had captured a strategic tower at Damietta. In September the expedition organized under papal auspices and consisting mainly of French Crusaders arrived under the Cardinal-legate Pelagius. Since Pelagius maintained that the Crusaders were under the jurisdiction of the church, he declined to accept the leadership of John of Brienne and often interfered in military decisions.

By February 1219, the Muslims were seriously alarmed and offered peace terms that included the cession of the Kingdom of Jerusalem, including the Holy City, as well as the return of the True Cross. King John and many of the Crusaders were eager to accept, but Pelagius, supported by the military orders and the Italians, refused. Damietta was finally taken on November 5, 1219, and for more than a year no further progress was made. Pelagius remained optimistic, still expecting the arrival of Holy Roman Emperor Frederick II—who had promised to go on Crusade in 1215—and convinced of the imminent approach of a legendary Asian Christian "King David." In July 1221 he ordered an advance on Cairo, which King John opposed but joined. Unfortunately, Pelagius, who knew nothing about the hydrography of the Nile, chose a campsite susceptible to the river's annual floods. Al-Malik al-Kāmil, the Egyptian sultan, opened the sluice gates and the Crusader army was hopelessly bogged down and forced to surrender. In return for their lives, the Crusaders agreed to evacuate Damietta and leave Egypt. It was a bitter defeat, for although Jerusalem had been at their fingertips throughout the Crusade, they were now forced to retreat with nothing.

Always on the verge of success, the Fifth Crusade failed largely because of divided leadership and the frequently unwise decisions of Pelagius. It might perhaps have succeeded if Frederick II had set out as promised, and it is sig-

Mission to the Muslims

nificant that disillusioned critics blamed the emperor and the pope as well as Pelagius. All in all, it was a dreary episode, relieved only by the presence of Francis of Assisi, whom Pelagius reluctantly permitted to cross the lines, where he was courteously received by al-Malik al-Kāmil. However, despite Francis's heartfelt plea, the Muslim leader declined his offer to convert to Christianity.

The Crusade of Frederick II. The failure of the Fifth Crusade placed a heavy responsibility on Frederick II, whose motives as a Crusader are difficult to assess. A controversial figure, he has been regarded by some as the archenemy of the popes and by others as the greatest of emperors. His intellectual interests included Islām, and his attitude might seem to be more akin to that of the Eastern barons than the typical Western Crusader. Through his marriage to John of Brienne's daughter Isabella (Yolande), he established a claim first to the kingship and then, on Isabella's death in 1228, to the regency of Jerusalem (Acre). As emperor he could claim suzerainty over Cyprus because his father and predecessor, Henry VI, was paid homage by the Cypriot king and bestowed a crown on him.

After being allowed several postponements by the pope to settle affairs in the empire, Frederick finally agreed to terms that virtually placed his expedition under papal jurisdiction. Yet his entire Eastern policy was inextricably connected with his European concerns: Sicily, Italy and the papacy, and Germany. Cyprus-Jerusalem became, as a consequence, part of a greater imperial design.

Most of his Crusade fleet left Italy in the late summer of 1227, but Frederick was delayed by illness. During the delay he received envoys from al-Malik al-Kāmil of Egypt, who, threatened by the ambitions of his Ayyūbid brothers, was disposed to negotiate. Meanwhile, Pope Gregory IX, less patient than his predecessor, rejected Frederick's plea that illness had hindered his departure and excommunicated the emperor. Thus, when Frederick departed in the summer of 1228 with the remainder of his forces, he was in the equivocal position of a Crusader under the ban of the church. He arrived in Cyprus on July 21.

In Cyprus, John of Ibelin, the leading member of the influential Ibelin family, had been named regent for the young Henry I. Along with most of the barons, he was willing to recognize the emperor's rights as suzerain in Cyprus. But because news of Isabella's death had arrived in Acre, the emperor could claim only a regency there for his infant son. John obeyed the emperor's summons to meet him in Cyprus but despite intimidation refused to surrender his lordship of Beirut and insisted that his case be brought before the high court of barons. The matter was set aside, and Frederick left for Acre.

In Acre, Frederick met more opposition. News of his excommunication had arrived, and many refused to support him. Dependent, therefore, on the Teutonic Knights and his own small contingent of German Crusaders, he was forced to attempt what he could by diplomacy. Negotiations, accordingly, were reopened with Al-Malik al-Kāmil.

The treaty of 1229

The treaty of 1229 is unique in the history of the Crusades. By diplomacy alone and without major military confrontation, Jerusalem, Bethlehem, and a corridor running to the sea were ceded to the Kingdom of Jerusalem. Exception was made for the Temple area, the Dome of the Rock, and the Aqṣā Mosque, which the Muslims retained. Moreover, all current Muslim residents of the city would retain their homes and property. They would also have their own city officials to administer a separate justice system and safeguard their religious interests. The walls of Jerusalem, which had already been destroyed, were not rebuilt, and the peace was to last for 10 years.

Nevertheless, the benefits of the treaty of 1229 were more apparent than real. The areas ceded were not easily defen-

King Louis IX of France embarking on the last Crusade to Tunis, 1270, from "History of Saint Louis," *c.* 1280

sible, and Jerusalem soon fell into disorder. Furthermore, the treaty was denounced by the devout of both faiths. When the excommunicated Frederick entered Jerusalem, the patriarch placed the city under interdict. No priest was present, and Frederick placed a crown on his own head while one of the Teutonic Knights read the ceremony. Leaving agents in charge, he hastily returned to Europe and at San Germano made peace with the pope (July 23, 1230). Thereafter, his legal position was secure, and the pope ordered the patriarch to lift the interdict.

Jerusalem and Cyprus, however, were now plagued by civil war because Frederick's imperial concept of government was contrary to the well-established preeminence of the Jerusalem baronage. The barons of both Jerusalem and Cyprus, in alliance with the Genoese and a commune formed in Acre that elected John of Ibelin as mayor, resisted the imperial deputies, who were supported by the Pisans, the Teutonic Knights, Bohemond of Antioch, and a few nobles. The clergy, the other military orders, and the Venetians stood aloof.

The barons were successful in Cyprus, and in 1233 Henry I was recognized as king. Even after John of Ibelin, the "Old Lord of Beirut," died in 1236, resistance continued. In 1243 a parliament at Acre refused homage to Frederick's son Conrad, unless he appeared in person, and named Alice, queen dowager of Cyprus, as regent.

Thus it was that baronial rule triumphed over imperial administration in the Levant. But the victory of the barons brought to the kingdom not strength but continued division, which was made more serious by the appearance of new forces in the Muslim world. The Khwārezmian Turks, pushed south and west by the Mongols, had upset the power balance and gained the support of Egypt. After the 10 years' peace had expired in 1239, the Muslims easily took back the defenseless Jerusalem. The Crusades of 1239 to 1241, under Thibaut IV of Champagne and Richard of Cornwall, brought about the return of the city as well as other lost territories through negotiation. However, in 1244 an alliance of Jerusalem and Damascus failed to prevent the capture and sack of Jerusalem by Khwārezmians with Egyptian aid. All the diplomatic gains of the preceding years were lost. Once again the Christians were confined to a thin strip of ports along the Mediterranean coast.

The Crusades of St. Louis. In June 1245, a year after the final loss of Jerusalem, Pope Innocent IV opened a great ecclesiastical council at Lyons. Although urgent appeals for help had come from the East, it is unlikely that the Crusade was uppermost in the pope's mind for a combination of crises confronted the church: numerous complaints of clerical abuses, increasing troubles with Frederick II in Italy, and the advance of the Mongols into eastern Europe. Nevertheless, when King Louis IX of France announced his intention to lead a new Crusade, the pope gave it his support and authorized the customary levy on clerical incomes.

Character of Louis IX

As a Crusader, Louis (who would be canonized in 1297) was the antithesis of Frederick. Possessed of a rare combination of religious devotion, firmness as a ruler, and bravery as a warrior, he seemed the very ideal of the Crusader. He was beloved by his subjects and respected abroad. He ardently believed the Crusade to be God's work, and he was far from sympathetic to the pope's use of Crusade propaganda against the emperor.

It was three years before Louis was ready to embark. Peace had to be arranged with England, transport had to be provided by Genoa and Marseilles, and funds had to be raised. When the king embarked in August 1248, he was accompanied by his queen; his brothers Robert of Artois and Charles of Anjou; many distinguished French nobles, including Jean de Joinville, author of the *Vie de St. Louis;* and a small English contingent. His army was a formidable one, numbering perhaps 15,000. France was left in the experienced hands of the queen mother, Blanche of Castile.

The Crusade arrived at Cyprus in September, and it was again decided to attack Egypt. Since a winter campaign was not feasible and Louis rejected the suggestion that he attempt negotiations, it was not until May 1249 that an expedition of some 120 large and many smaller vessels got under way. Fortune favoured them at first, and Damietta was again in Christian hands by June. Shortly afterward, the army was strengthened by the arrival of Louis's third brother, Alphonse of Poitiers. Sultan Sālih-Ayyūb's death was followed by confusion in Cairo, which, after some argument, had become the Crusaders' objective. In February 1250 Robert of Artois led a surprise attack on the Egyptian camp two miles (three kilometres) from Al-Mansūrah, but, rejecting the advice of more-experienced campaigners and acting impetuously, he was trapped within the city. Many knights lost their lives. Louis soon arrived with the main army and won another victory, albeit a costly one, near Al-Mansūrah. It was the last Crusader success.

Meanwhile, Tūrān-Shāh, the sultan's son, had returned from Diyarbakır (now in Turkey) to Cairo and temporarily dominated dissident factions there. Frankish supply ships from Damietta were intercepted, and before long the Crusaders were suffering from famine and disease. Louis, reluctant to abandon a work to which he had dedicated his very kingdom, perhaps delayed too long before ordering a retreat. Refusing the pleas of others to protect himself by fleeing, he remained to lead his soldiers and was captured with many of them as the Muslim forces closed in.

The capture of Louis

The king and nobles were held for ransom, but many non-noble captives were killed. The queen, who had just given birth to a son sorrowfully named John Tristan, managed with great courage to secure sufficient food and to persuade the Genoese and Pisans not to evacuate Damietta until it could be ceded formally by treaty and the king's ransom arranged. On May 6, 1250, the king was released, and Damietta surrendered.

Despite the pleadings of his advisers, Louis did not return home immediately. He felt bound in conscience to negotiate the release of as many prisoners as possible, and he also improved the defenses of the kingdom by strengthening a number of fortifications before he left in April 1254. Thus, he atoned in some small measure for the failure of the Crusade and returned to France, determined to lead a life as a Christian king worthy of rescuing Jerusalem one day.

During these same years a group of Mongols under Hülegü overran Mesopotamia and in 1258 took Baghdad, thus ending the venerable ʿAbbāsid caliphate. In 1260, the Mamlūks of Egypt, a new dynasty that had arisen from the leaders of former slave bodyguards of the sultan, defeated the Mongols at ʿAyn Jālūt in Syria and halted their southward advance. The Muslim states of Syria were caught in the middle, and the Latin states were in grave danger. King Hayton of Armenia and his son-in-law Bohemond VI of Antioch-Tripoli allied themselves with the Mongols. But the barons at Acre were still more disposed to deal with the Muslims, whom they knew, than with the terrifying and unknown Mongols.

In 1260, after murdering his predecessor, Baybars became sultan of Egypt. Though this famous Mamlūk sultan did not live to see the fall of the Latin states before his death in 1277, he did reduce them to a few coastal outposts. Baybars was ruthless, utterly lacking the generous chivalry that the Crusaders had admired in Saladin. Most of his conquests were followed by a general massacre of the inhabitants. In 1265, he took Caesarea, Haifa, and Arsuf. The following year he conquered Galilee and devastated Cilician Armenia. In 1268, Antioch was taken and all the inhabitants slaughtered. The great Hospitaller fortress of Krak des Chevaliers fell three years later.

Baybars captures Antioch

These disasters again brought pleas for aid from the West. King Louis once again took up the cross, but his second venture never reached the East. The expedition instead went to Tunis, probably because of the influence of Louis's brother, Charles of Anjou, who had recently been named by the papacy as the successor to the Hohenstaufens in Sicily. In 1268 he defeated Conradin, the last of the Hohenstaufen line, and was soon involved in grandiose Mediterranean projects, which ultimately included even Byzantium.

Louis's new Crusade embarked from southern France in July 1270. Soon after the French landed in North Africa, however, disease struck the troops and claimed the lives of both Louis and his son John Tristan. Charles arrived with the Sicilian fleet in time to bargain for an indemnity to

evacuate the remnants of the army. Thus, the Crusade ended in tragedy and brought no help to the East. Nevertheless, despite two failures, Louis IX became for all Christians the model of the selfless warrior of Christ. Although the expansion of Muslim power seemed increasingly unstoppable, Europeans continued to embrace the idea of the Crusades and to pray for their success.

The final loss of the Crusader states. By the end of the 13th century, Crusading had become more expensive. The time had passed when a Crusader army was made up of knights who served under a lord and paid their own way. Economic pressures caused many nobles to seek royal service. Royal armies, therefore, became more professional, and many knights as well as foot soldiers served for pay. Moreover, the rise of royal authority meant that great Crusades could no longer be cobbled together by feudal lords but were increasingly reliant on kings, who were by their nature easily distracted by events at home.

In the East, chronic divisions, similar to those in Europe, were a major cause of the Crusader kingdom's downfall. From the time of Frederick II, the kingdom had been governed by absentee rulers; at first, the Hohenstaufens were represented in the East by agents, and after 1243 by regents of the Jerusalem dynasty chosen by the high court of barons. In 1268, on the death of the last Hohenstaufen, the crown was given to Hugh III of Cyprus, who returned to the island in 1276 thoroughly frustrated. Then in 1277 Charles of Anjou, as part of his attempt to create a Mediterranean-wide empire and with papal approval, bought the rights of the nearest claimant and sent his representative. Finally, after Charles's death in 1285, the barons once again chose a native ruler, Henry II of Cyprus.

Successive regents had failed to control the Jerusalem baronage, ultimately resulting in the disintegration of the entire structure of Outremer into separate parts. Antioch-Tripoli before its fall had been increasingly aloof and through intermarriage closely tied to Armenia. In Acre, the seat of government of the kingdom, there was a commune of barons and bourgeois. Immigration had ceased, and the barons were now reduced in numbers as old families had died out. Some resided in Cyprus, and others were nominal lords in Palestine of fiefs actually under Muslim control. The military orders, habitually in conflict, were virtually distinct entities with extensive connections in Europe. The bourgeois population had also considerably altered in composition during the 13th century. The earlier French predominance in the region had given way to an Italian one. But the Italians of Outremer were as divided as they were in Italy. The Genoese-Venetian rivalry extended to the Levant and occasionally, as in Acre in 1256, resulted in outright war.

The papacy's concern for Outremer was not confined to efforts to enlist military aid. Papal financial support was continuous, and the popes exchanged diplomatic envoys with Eastern rulers, both Muslim and Mongol. Furthermore, the 13th-century patriarchs of Jerusalem, commonly named by the pope, were also papal legates. But no absentee king, pope, or patriarch-legate could bring to the Latin East the unity necessary for its survival.

The death of Baybars in 1277, therefore, brought only temporary respite for the Crusaders, who remained divided and isolated. In 1280 they again failed to join the Mongols, whom Sultan Qalāʾūn defeated in 1281. The ineffectiveness of the Jerusalem administration was becoming apparent even to Easterners, and the Il-Khan Abagha, the Mongol leader in Iran, sent his deputy Rabban Sauma to the kings of Europe and the pope to seek an alliance. The effort was fruitless. Tripoli fell in 1289, and Acre, the last Crusader stronghold on the mainland, was besieged in 1291. After a desperate and heroic defense, the city was taken by the Mamlūks, and the inhabitants who survived the massacre were enslaved. Acre and all the castles along the Mediterranean coast were systematically destroyed.

The fall of Tripoli and Acre

A growing sense of their isolation may have been the reason that the Franks of the 13th century did not develop further the distinctive culture of their predecessors. The remarkable palace of the Ibelins in Beirut, built early in the century, boasted Byzantine mosaics. But, partly because of King Louis's four-year stay in the kingdom, remains of churches and castles indicate a close following of adherence to French Gothic architectural style. Literary tastes were also distinctly French, and the production of manuscripts followed French traditions. At the coronation festivities for Henry II in 1286, in total disregard—or perhaps in chivalrous defiance—of the ruin surrounding them, the nobles amused themselves by acting out the romances of Lancelot and Tristan.

The greatest cultural achievement of the Second Kingdom was the collection of legal treatises, the *Assises de Jérusalem*. The sections that were compiled in the middle years of the century and, therefore, in the atmosphere of the wars against the agents of Frederick II constitute a veritable charter of baronial rights. In fact, two of the authors were members of the Ibelin family, and a third, Philip of Novara, was a close associate. These sections indicate a shift from the earlier *Livre au roi* ("Book of the King"), which more nearly reflects the attitudes of the 12th century. Nevertheless, the *Assises* belong to medieval Europe's legal renaissance.

The later Crusades

Europe was dismayed by the disaster of 1291. Pope Nicholas IV had tried to organize aid beforehand, and he and his successors continued to do so afterward, but without success. France, which had always been the main bulwark of the Crusades, was in serious conflict with England, which led to the outbreak of the Hundred Years' War in 1337. Moreover, the continued decline of papal authority and rise of royal power meant that most of Europe's warriors were busy at home. The best that the church could do was to organize smaller Crusade expeditions with very limited goals.

In the East, the military orders could no longer offer a standing nucleus of troops. In 1308 the Hospitallers took Rhodes and established their headquarters there. In 1344, with some assistance, they occupied Smyrna, which they held until 1402. Meanwhile, the Teutonic Knights had moved their operations to the Baltic area. The Templars were less fortunate. In 1308 the French Templars were arrested by Philip IV, and in 1312 the order was suppressed by Pope Clement V. Finally, in 1314, Jacques de Molay, the order's last grand master, was burned at the stake.

Suppression of the Templars

It is not surprising, therefore, that papal calls to Crusade were answered largely in the form of Crusade theories. For some years after 1291 various projects were proposed, all designed to avoid previous mistakes and explore new tactics. The Franciscan missionary Ramon Llull, for example, in his *Liber de fine,* suggested a campaign of informed preaching as well as military force. At the beginning of the 14th century, Pierre Dubois submitted a detailed scheme for a Crusade to be directed by Philip IV of France, and in 1321 Marino Sanudo, in his *Secreta fidelium crucis,* produced an elaborate plan for an economic blockade of Egypt. But none of these or any other such schemes was put into effect.

King Peter I of Cyprus finally organized an expedition that in 1365 succeeded in the temporary occupation of Alexandria. After a horrible sack and massacre, the unruly Crusaders returned to Cyprus with immense booty. Peter planned to return, but no European aid was forthcoming.

With the failure of all attempts to regain a foothold on the mainland, Cyprus remained the sole Crusader outpost, and after 1291 it was faced with a serious refugee problem. It was in Cyprus that many of the institutions established by the Franks survived. For, although Jerusalem and Cyprus normally had separate governments, through intermarriage and the exigencies of diplomacy the histories of the two had become interwoven. Regents of one were often chosen from among relatives in the other. It has been noted that many Jerusalem barons resided in Cyprus. With suitable modifications, the *Assises de Jérusalem* applied on the island, and, on the mainland, the French character of the Cypriot Latins is evident in the remains of Gothic structures.

In one respect Cyprus did differ from the mainland. Whereas the First Kingdom had established a modus vivendi with its native population, such was not the case in

the island kingdom. Many Greek landholders had fled, and those who remained suffered a loss of status. All Greeks resisted the Latinizing efforts of the early 13th-century popes and their representatives. Innocent IV was more flexible, but tension persisted until the Turkish conquest in the 16th century.

Growth of Ottoman power

As the Ottoman Turks expanded their power in the Levant, they took an increasingly larger role in Byzantine politics. During a civil war in 1348, Emperor John Cantacuzenus allowed the Turks to cross the Dardanelles into Greece. The gates to Europe, so long defended by Constantinople, were now opened to a powerful Muslim empire, and waves of Turks crossed over. By the end of the 14th century, they had conquered all of Bulgaria and most of Greece and had surrounded Constantinople. The rapid expansion of the Turks into Christian Europe changed the nature of the Eastern Crusades. No longer aimed at conquering faraway Palestine, they became desperate attempts to defend Europe itself.

One of the greatest efforts to repulse the Turkish advance was the Crusade of Nicopolis. Prompted by a plea from King Sigismund of Hungary in 1395, the Crusade was joined by powerful Burgundian and German armies who rendezvoused at Buda the following year. Although it was one of the largest crusading forces ever assembled, the Crusade was crushed utterly by the army of Sultan Bayezid I. Hungary was left virtually defenseless, and the smashing defeat of the Crusade of Nicopolis led many to fear that all of Europe would soon succumb to the Muslim advance.

Shorn of its empire, Constantinople continued to hold out against the Turks, but it could not do so for long without aid. Emperor John VIII, the patriarch of Constantinople, and members of the Greek clergy traveled to the West in 1437 to attend the Council of Florence. The disputes that had separated the Latin and Greek churches were frankly debated at the council. The Latin side won out, however, because the Greeks desperately needed Western help to save Constantinople. Even though the emperor and patriarch accepted papal primacy and the reunification of the churches was solemnly declared, the Greek people refused to accept submission to Rome.

Shortly after the Council of Florence, Pope Eugenius IV organized a Crusade to relieve Constantinople. Recruits mainly from Poland, Wallachia, and Hungary joined the so called Crusade of Varna, which was led by János Hunyadi, the ruler of Transylvania, and King Władysław III of Poland and Hungary. In 1444, the force of some 20,000 men entered Serbia and captured Niš. Sultan Murad II offered Hungary a 10-year truce, which was ultimately refused. He then led his forces to Varna in Bulgaria, which the Crusaders were in the process of besieging, and destroyed the Christian army. The king of Hungary and the papal legate were killed in the carnage. Nine years later, Constantinople at last fell to the Ottoman Turks. Riding triumphantly into the city, Sultan Mehmed II made it clear that he was determined to conquer Rome as well.

Fall of Constantinople

Mehmed almost made good on that threat. In 1480, he launched two major offensives against the Christians. The first, a massive siege of the Hospitallers on Rhodes, failed. The second, an invasion of Italy, met with more success. The city of Otranto was captured, providing the Turks with a strategic beachhead on the peninsula. Panic broke out in Rome as people packed their bags and prepared to flee the city. Pope Sixtus IV issued a call for a Crusade to defend Italy, but only Italians took an interest. Fate stepped in, however, when the sultan died on May 3, 1481. Turkish attention shifted to a power struggle for the throne, thus allowing a papal fleet to recapture Otranto.

Only in Spain did Crusades meet with regular success. The unification of Aragon and Castille under Ferdinand and Isabella in 1479 gave Christian knights the opportunity to take up the cross against the remaining Muslims in Iberia. The campaigns continued throughout the 1480s and led to the surrender of Grenada, the last Muslim stronghold, on January 12, 1492. Nearly 800 years after the first effort to expel the Muslims, the Reconquista was completed. Christians across Europe rang church bells and marched in processions of thanksgiving.

Crusading came to an end in the 16th century, mainly because of changes in Europe brought on by the advent of the Protestant Reformation and not because the Muslim threat had diminished. Martin Luther and other Protestants had no use for Crusades, which they believed were cynical ploys by the papacy to grab power from secular lords. Protestants also rejected the doctrine of indulgence, central to the idea of the Crusade. Despite the decline in the appeal of Crusading, the popes continued to call for peace in Europe so that Crusades could be launched against the Turks and often financed such wars in holy leagues with various states like Venice or Spain. One such league won a dramatic victory against the Ottoman fleet at Lepanto in 1571. The Battle of Lepanto, although not militarily decisive, did give new hope to Europeans who saw for the first time that it was indeed possible to defeat the Turks.

A few last vestiges of the Crusading movement, however, survived its demise. The Knights Hospitaller, ejected from Rhodes by Sultan Süleyman the Magnificent in 1522, moved to the island of Malta, where they continued to take part in holy leagues. They also remained true to their mission to care for the poor and sick and built a great hospital at Valletta on Malta that attracted patients from across Europe. The Knights retained the island until 1798, when Napoleon expelled them. They then moved to Rome, where they became a government in exile. Known today as the Knights of Malta, they still issue passports and are recognized as a sovereign state by some countries. More important, around the world the Knights continue to devote themselves to the care of the poor and sick.

The Teutonic Knights declined after they were defeated by Poland and Lithuania in 1410. In 1525, the grand master, under Protestant influence, dissolved the order in Prussia and took personal control of its lands as a vassal of the king of Poland. The order was officially dissolved in 1809. The Austrian emperor reestablished the Teutonic Order as a religious institution in 1834, headquartering it in Vienna, where it remains today doing charitable work and caring for the sick.

The results of the Crusades

The entire structure of European society changed during the 12th and 13th centuries, and there was a time when this change was attributed largely to the Crusades. Historians now, however, tend to view the Crusades as only one, albeit significant, factor in Europe's development. It is likely that the disappearance of old families and the appearance of new ones can be traced in part to the Crusades, but generalizations must be made with caution. It should, moreover, be remembered that, while some Crusaders sold or mortgaged their property, usually to ecclesiastical foundations, others bequeathed it to relatives. The loss of life was without doubt considerable; many Crusaders, however, did return to their homes.

Economic and social impact on Europe

The sectors acquired by burgeoning Italian cities in the Crusader states enabled them to extend their trade with the Muslim world and led to the establishment of trade depots beyond the Crusade frontiers, some of which lasted long after 1291. The transportation they provided was significant in the development of shipbuilding techniques. Italian banking facilities became indispensable to popes and kings. Catalans and Provençals also profited, and, indirectly, so did all of Europe. Moreover, returning Crusaders brought new tastes or increased the demand for spices, Oriental textiles, and other exotic fare. But such demands can also be attributed to changing lifestyles and commercial growth in Europe itself.

The establishment of the Franciscan and Dominican friars in the East during the 13th century made possible the promotion of missions within the Crusade area and beyond. Papal bulls granted special facilities to missionary friars, and popes sent letters to Asian rulers soliciting permission for the friars to carry on their work. Often the friars accompanied or followed Italian merchants, and, since the Mongols were generally tolerant of religious propaganda, missions were established in Iran, the Asian interior, and even China. But, since Islāmic law rigidly prohibited propaganda and punished apostasy with death, conver-

sions from Islām were few. The Dominican William of Tripoli had some success, presumably within the Crusaders' area; he and his colleague, Ricoldus of Montecroce, both wrote perceptive treatises on Islāmic faith and law. Other missionaries usually failed, and many suffered martyrdom. In the 14th century, the Franciscans were finally permitted to reside in Palestine as caretakers for the holy places but not as missionaries.

The Crusades, especially the Fourth, so embittered the Greeks that any real reunion of the Eastern and Western churches was, as a result, out of the question. Nonetheless, certain groups of Eastern Christians came to recognize the authority of the pope, and they were usually permitted to retain the use of their native liturgies. Although the majority of the missions that grew out of the Crusades collapsed with the advance of the Ottoman Turks in the Middle East in the mid-14th century, some of the contacts which the Western church had made with its Eastern brethren remained.

Unlike Sicily and Spain, the Latin East did not, it seems, provide an avenue for the transmission of Arabic science and philosophy to the West. But the Crusades did have a marked impact on the development of Western historical literature. From the beginning there was a proliferation of chronicles, eyewitness accounts, and later more ambitious histories, in verse and in prose, in the vernacular as well as in Latin.

There can be little doubt that the Crusades slowed the advance of Islāmic power, although how much is an open question. At the very least, they bought Europe some much needed time. Without centuries of Crusading effort, it is difficult to see how western Europe could have escaped conquest by Muslim armies, which had already captured the rest of the Mediterranean world. (T.F.M./M.W.B.)

Crusade as metaphor

One of the most enduring, though least discussed, results of the Crusades was the shift from the Crusade as history, that is, as a series of actual historical events, to the Crusade as metaphor, when the actual Crusades had ceased and all that was left was the word. The transformation of the idea of the Crusades from religio-military campaigns into modern metaphors for idealistic, zealous, and demanding struggles to advance the good ("crusades for") and to oppose perceived evil ("crusades against") occurred over several centuries and represents the culmination of a movement that began in the late 11th century. By the early 12th century, historiography was already contributing to the idea of the Crusade as armed pilgrimage or holy war, which Bernard of Clairvaux in the mid-12th century and Pope Innocent III in the early 13th continued to elaborate. Receptive to chivalric as well as Christian ideals, crusade ideology proved more durable than the stinging criticisms provoked by successive military defeats, culminating in the loss of the Holy Land in 1291.

The evolution of the idea of Crusade

The intermittent continuation of the movement during the later Middle Ages led to proposals for new Crusades. Some were grounded in strategic realities, others in utopian or prophetic aspirations, which emphasized certain moral or political prerequisites as essential to regaining Jerusalem. European intellectuals thus began to reinvent the Crusades. In the early 14th century, Pierre Dubois devised a plan for the French king to seize control of Christendom from the pope and lead a victorious Crusade. Christopher Columbus imagined that a messianic Spanish ascendancy would reconquer Constantinople, then Jerusalem. Viewed as a solution to the woes of Europe, proposals for Crusades against the Ottoman Turks continued to be put forward from the Reformation to the age of Louis XIV.

Continuing interest in the Crusades meant that they never disappeared from public consciousness. During the Enlightenment, when medieval Crusading was perceived as irrational fanaticism, and in the Romantic era, when the Crusades were seen as an adornment of the faith and an embodiment of chivalry, the Crusades never ceased to attract the attention of historians, poets, novelists, composers, and encyclopaedists. Accordingly, the emergence of the Crusades as metaphor by the latter half of the 18th century implies at least some knowledge of the historical Crusades. English dictionaries were slow to register the change, however. Neither the *Dictionary* of Samuel Johnson (1755) nor that of Noah Webster (1828, rev. 1845) includes a metaphorical definition of *crusade*. Anticipating later lexicographers, however, a future president of the United States was already using the Crusade metaphor in 1786. Writing to the jurist George Wythe, Thomas Jefferson urged: "Preach, my dear Sir, a crusade against ignorance; establish and improve the law for educating the common people." The source of Jefferson's positive use of the Crusade as metaphor—to which Americans have ever since remained faithful—remains uncertain. Although he had histories of the Crusades by Louis Maimbourg (1682) and Voltaire (1756) in his well-stocked library, Jefferson would not have been inspired by these works because of their negative attitude toward the Crusades. Marie-Jean-Antoine-Nicholas de Caritat Condorcet's progressivist interpretation of the Crusades in his *Esquisse d'un tableau historique des progrès de l'esprit humain* (1795; *Sketch for a Historical Picture of the Progress of the Human Mind*) postdates Jefferson's metaphor and cannot have been the inspiration for it. Whatever the origin of Jefferson's usage, the Crusade metaphor had become so well-established in American usage by 1861 that E.G. de Fontaine was able to deploy it ironically against his enemies, the abolitionists, who, he sneered, "invited all men to join in the holy crusade" against slavery.

Modern crusades

The titles of 20th-century English-language books demonstrate just how popular Crusade metaphors would become, encompassing crusades against tuberculosis, drink, crime, capital punishment, drug abuse, and poverty, along with crusades for justice, education, total freedom, humanity, women's rights, and the environment. The metaphor was used by both sides in the Spanish Civil War and has also been applied to Billy Graham's campaign of evangelism. It also has been used to describe various U.S. government domestic and foreign policy initiatives. But perhaps the best-known use of the metaphor in the 20th century was by Dwight D. Eisenhower, whose 1948 memoir of World War II, *Crusade in Europe,* applied the term to the great struggle against the Nazis.

Metaphors empower language and thought; they also risk oversimplifying and distorting historical truth and trivializing their subject through repetition. Moreover, metaphors are culturally specific and often convey value judgments. While modern historians attempt to understand the Crusades by placing them in the context of medieval religion, culture, and society, popular metaphorical usage dehistoricizes the Crusades into ongoing, eternal, yet contemporary conflicts of good versus evil—against AIDS, drugs, poverty, terrorism, etc. American crusades have been exclusively metaphorical, and nearly always, from Jefferson's day to the present, they have carried positive connotations. For many Arabs and Muslims, however, the Crusades can have highly negative associations of medieval Christian aggression and modern Western imperialism and colonialism. In other words, the ultimate power, significance, and meaning of the Crusades and its usefulness as a metaphor depend, in the end, on one's cultural heritage and point of view. (G.D.)

BIBLIOGRAPHY

General works. A good bibliographic introduction to work on the Crusades, including sources, secondary studies, and journal articles, is found in H.E. MAYER and JOYCE MCLELLAN, "Select Bibliography of the Crusades," in KENNETH M. SETTON (gen. ed.), *A History of the Crusades,* vol. 6 (1989), pp. 511–664. The best full-scale treatments of the Crusades in English are STEVEN RUNCIMAN, *A History of the Crusades,* 3 vol. (1951–54); JONATHAN RILEY-SMITH, *The Crusades: A Short History* (1987); H.E. MAYER, *The Crusades,* 2nd ed. (1988); JEAN RICHARD, *The Crusades* (1999); and THOMAS F. MADDEN, *A Concise History of the Crusades* (1999). The long-neglected Muslim side of the story is examined by CAROLE HILLENBRAND, *The Crusades: Islamic Perspectives* (2000). The multivolume collection, KENNETH M. SETTON (ed.), *A History of the Crusades,* 2nd ed. (1969–89), is a cooperative work by a number of historians on a host of topics.

Useful selections of sources in English translation are JAMES A. BRUNDAGE, *The Crusades: A Documentary Survey* (1962);

FRANCESCO GABRIELI (compiler), *Arab Historians of the Crusades* (1969, reissued 1992; originally published in Italian, 1957); RÉGINE PERNOUD, *The Crusades* (1962; originally published in French, 1960); and LOUISE RILEY-SMITH and JONATHAN RILEY-SMITH, *The Crusades: Idea and Reality, 1095–1274* (1981).

Crusades in the 11th and 12th centuries. The idea of the Crusade is explored in CARL ERDMANN, *The Origin of the Idea of Crusade* (1977; originally published in German, 1935), a classic in the history of the Crusades. Interpretations and factors are discussed in PAUL ALPHANDÉRY, *La chrétienté et l'idée de croisade,* 2 vol. (1954–59); JAMES A. BRUNDAGE, *Medieval Canon Law and the Crusader* (1969); and JONATHAN RILEY-SMITH, *The First Crusade and the Idea of Crusading* (1986). The best works on the First Crusade are RILEY-SMITH's work cited above as well as his *The First Crusaders, 1095–1131* (1997).

Studies that illuminate other factors in the Crusade are JOHN FRANCE, *Victory in the East: A Military History of the First Crusade* (1994); and MARCUS BULL, *Knightly Piety and the Lay Response to the First Crusade* (1993). The attacks on the Jews during the First Crusade are discussed in ROBERT CHAZAN, *European Jewry and the First Crusade* (1987, reissued 1996) and *In the Year 1096: The First Crusade and the Jews* (1996). A useful treatment of the Third Crusade can be found in JOHN GILLINGHAM, *Richard I* (1999).

Crusader states. There are many excellent studies on the history of the Crusader states. Among these are DANA C. MUNRO, *The Kingdom of the Crusaders* (1935, reprinted 1966); JOHN L. LaMONTE, *Feudal Monarchy in the Latin Kingdom of Jerusalem, 1100 to 1291* (1932, reprinted 1970); JEAN RICHARD, *The Latin Kingdom of Jerusalem,* 2 vol. (1979; originally published in French, 1953); JOSHUA PRAWER, *The Latin Kingdom of Jerusalem: European Colonialism in the Middle Ages* (1973); RALPH-JOHANNES LILIE, *Byzantium and the Crusader States, 1096–1204* (1993); JONATHAN PHILLIPS, *Defenders of the Holy Land: Relations between the Latin East and the West, 1119–1187* (1996); RONNIE ELLENBLUM, *Frankish Rural Settlement in the Latin Kingdom of Jerusalem* (1998); and BERNARD HAMILTON, *The Leper King and His Heirs: Baldwin IV and the Crusader Kingdom of Jerusalem* (2000).

Crusades in the 13th century. The Fourth Crusade is described by DONALD E. QUELLER and THOMAS F. MADDEN, *The Fourth Crusade: The Conquest of Constantinople,* 2nd ed. (1997); from the Byzantine perspective, in CHARLES M. BRAND, *Byzantium Confronts the West, 1180–04* (1968); and from the Venetian perspective, in THOMAS F. MADDEN, *Enrico Dandolo and the Rise of Medieval Venice* (2002). For the Fifth Crusade, see JAMES M. POWELL, *Anatomy of a Crusade, 1213–1221* (1986); and the older, but still useful, JOSEPH P. DONOVAN, *Pelagius and the Fifth Crusade* (1950). The best treatment of the Crusades of St. Louis can be found in JEAN RICHARD, *Saint Louis: Crusader King of France* (1992). WILLIAM CHESTER JORDAN, *Louis IX and the Challenge of the Crusade* (1979) places the two Crusades within the framework of Louis's reign.

Later Crusades. The single best resource for the later Crusades is KENNETH M. SETTON's magisterial *The Papacy and the Levant (1204–1571),* 4 vol. (1976–84). Also important are NORMAN HOUSLEY, *The Avignon Papacy and the Crusades, 1305–1378* (1986) and by the same author, *The Later Crusades, 1274–1580: From Lyons to Alcazar* (1992).

Crusades in the West. For the Spanish Reconquista, see DEREK W. LOMAX, *The Reconquest of Spain* (1978); and BERNARD F. REILLY, *The Contest of Christian and Muslim Spain, 1031–1157* (1992). The best work on the Albigensian Crusade is JOSEPH R. STRAYER, *The Albigensian Crusades,* with a new epilogue by CAROL LANSING (1992).

Special topics. Military histories of the Latin East are available in R.C. SMAIL, *Crusading Warfare, 1097–1193,* 2nd ed. (1995) and CHRISTOPHER MARSHALL, *Warfare in the Latin East, 1192–1291* (1992). Art and architecture of the Latin East is discussed by T.S.R. BOASE, *Kingdoms and Strongholds of the Crusaders (1971);* HUGH KENNEDY, *Crusader Castles* (1994); and JAROSLAV FOLDA, *The Art of the Crusaders in the Holy Land* (1995). For histories of the military orders, see MALCOLM BARBER, *The New Knighthood: A History of the Order of the Temple* (1994); JONATHAN RILEY-SMITH, *The Knights of St. John in Jerusalem and Cyprus, c. 1050–1310* (1967); ERIC CHRISTIANSEN, *The Northern Crusades: The Baltic and Catholic Frontier, 1100–1525,* 2nd ed. (1997). (T.F.M./M.W.B./Ed.)

Crusade as metaphor. The history of the metaphoric use of the term Crusade is addressed in several works cited above. Other useful studies are PAUL ROUSSET, *Histoire d'une idéologie, la Croisade* (1983); GILES CONSTABLE, "The Historiography of the Crusades," in ANGELIKI E. LAIOU and ROY PARVIZ MOTTAHEDEH (eds.), *The Crusades from the Perspective of Byzantium and the Muslim World* (2001); and JAMES A. BRUNDAGE (ed.), *The Crusades: Motives and Achievements* (1964). A thoughtful introduction to the use of metaphor is GEORGE LAKOFF and MARK JOHNSON, *Metaphors We Live By* (1980). (G.D.)

Crustaceans

Crustacea is a subphylum of the animal phylum Arthropoda. Crabs, lobsters, shrimps, and wood lice are the best-known crustaceans, but the group also includes an enormous variety of other forms without popular names. Crustaceans are generally aquatic and differ from other arthropods in having two pairs of appendages (antennules and antennae) in front of the mouth and paired appendages near the mouth that function as jaws. Because there are many exceptions to the basic features, a satisfactory inclusive definition of all the Crustacea is extraordinarily hard to frame.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 313, and the *Index.*

This article is divided into the following sections:

CRUSTACEANS: SUBPHYLUM CRUSTACEA

GENERAL FEATURES

Size range and diversity of structure. The largest crustaceans belong to the Decapoda, an order that includes the American lobster, which can reach a weight of 20 kilograms (44 pounds), and the giant Japanese spider crab, which has legs that can span up to 3.7 metres (12 feet). At the other end of the scale, some of the water fleas (class Branchiopoda), such as *Alonella,* reach lengths of less than 0.25 millimetre (0.009 inch), and many members of the subclass Copepoda are less than one millimetre in length. The range of structure is reflected in the complex classification of the group (Figure 1). Some of the parasitic forms are so modified and specialized as adults that they can only be recognized as crustaceans by features of their life histories.

Aquatic habitats

Distribution and abundance. Crustaceans are found mainly in water. As a group they range from fresh water to seawater and even into inland brines, which may have several times the salt concentration of seawater. Various species have occupied almost every conceivable niche within the aquatic environment. An enormous abundance of free-swimming (planktonic) species occupies the open waters of lakes and oceans. Other species live at the bottom of the sea, where they may crawl over the sediment or burrow into it. Different species are found in rocky, sandy, and muddy areas. Some species are so small that they live in the spaces between sand grains. Others tunnel in the fronds of seaweeds or into man-made wooden structures. Some members of the orders Isopoda and Amphipoda extend down to the greatest depths in the sea and have been found in oceanic trenches at depths of up to 10,000 metres. Crustaceans colonize lakes and rivers throughout the world, even high mountain lakes at altitudes of 5,000 metres. They range widely in latitude as well: in the high Arctic some crustaceans use the short summer to develop quickly through a generation, leaving dormant stages to overwinter.

A number of crabs are amphibious, being capable of leaving the water to scavenge on land. Some, like the ghost crabs (*Ocypode*), can run at great speed across tropical beaches. One of the mangrove crabs, *Aratus,* can climb trees. Some crabs spend so much time away from the water that they are known as land crabs; however, these crustaceans must return to the water when their eggs are ready to hatch. The most terrestrial of the Crustacea are the wood lice (order Isopoda, family Oniscoidea), most of which live in damp places, although a few species can survive in deserts. In addition to these well-adapted groups, occasional representatives of other groups have become at least semiterrestrial. Amphipods, members of the subclasses Copepoda and Ostracoda, and the order Anomopoda have been found among damp leaves on forest floors, particularly in the tropics.

Terrestrial species

Importance to humans. The crustaceans of most obvious importance to humans are the larger species, chiefly decapods. Fisheries in many parts of the world capture shrimps, prawns, spiny lobsters, and the king crab (*Paralithodes*) of the northern Pacific and its southern counterpart, the centolla, found off the coast of Chile. Many species of true crabs—such as the blue crab, Dungeness crab, and the stone crab, all in North America, and the edible crab of Europe—are valuable sources of food. The most highly prized decapod is probably the true lobster (*Homarus* species), although overfishing since the early 20th century has greatly diminished the catches of both the North American and the European species. Freshwater crustaceans include crayfish and some river prawns and river crabs. Many species have only local market value. It is probable that no crustaceans are poisonous unless they have been feeding on the leaves or fruits of poisonous plants.

Edible crustaceans

The large acorn shell (*Balanus psittacus*), a barnacle (order Cirripedia) measuring up to 27 centimetres (11 inches) in length, is regarded as a delicacy in South America, and a stalked barnacle (*Mitella pollicipes*) is eaten in parts of France and Spain. In Japan, barnacles are allowed to

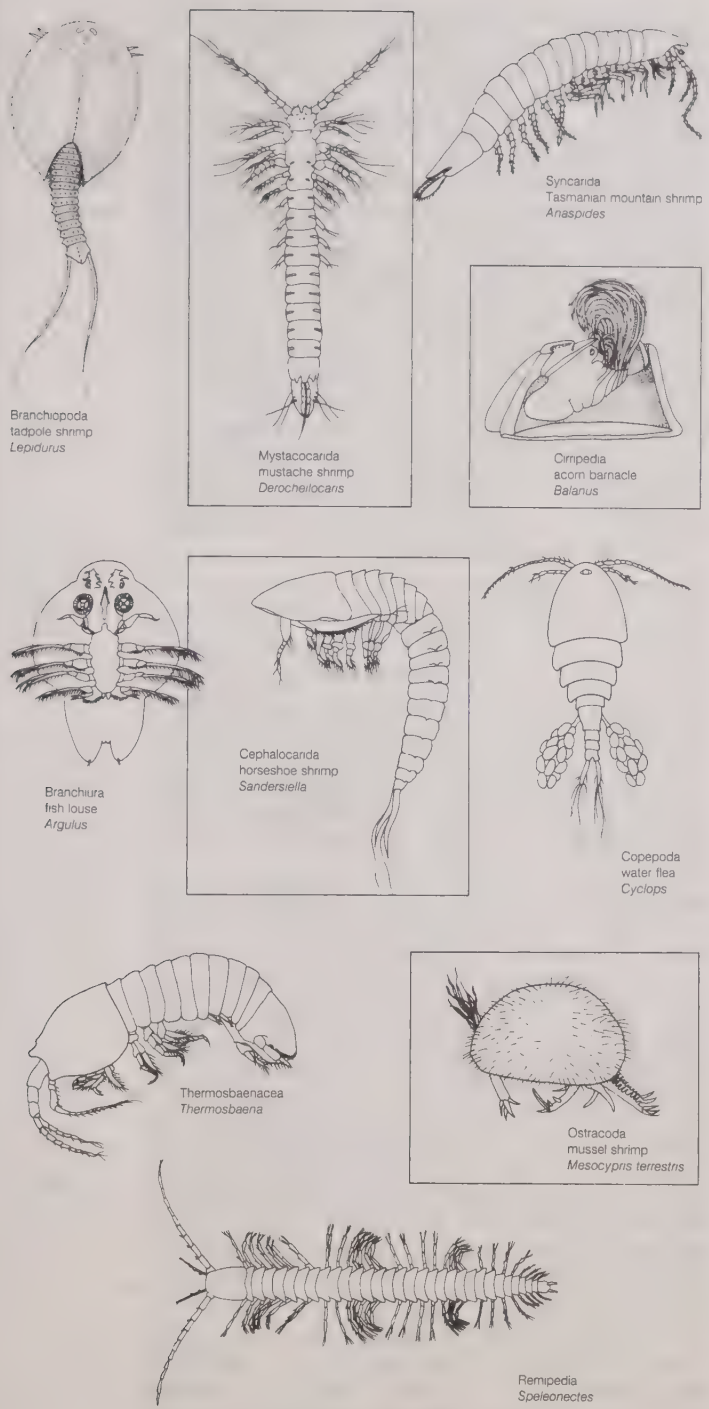

Figure 1: Body plans of representative crustaceans (branchiopod, mystacocarid, syncarid, cirripede, branchiuran, cephalocarid, copepod, thermosbaenid, ostracod, and remipedia).

After (*Anaspides*) Siewing and (*Thermosbaena*) Monod in A. Kaestner, *Invertebrate Zoology* (1970), John Wiley & Sons, Inc.; from (*Mesocypris terrestris*) *Memoires of the Institut Francais d'Afrique Noire* (1966), (*Speleonectes*) J. Yager in L. Botosaneanu (ed.), *Stygofauna Mundi* (1986), E. J. Brill, Leiden; (others except *Lepidurus*) *Invertebrate Zoology* by Paul A. Meglitsch, copyright © 1967 by Oxford University Press, Inc., reprinted by permission

settle and grow on bamboo stakes, later to be scraped off and crushed for use as fertilizer. Planktonic (*i.e.,* drifting) copepods, such as *Calanus* and members of the order Euphausiacea (euphausiids), or krill, may be present in such great numbers that they discolour large areas of the open sea, thus indicating to fishermen where shoals of herring and mackerel are likely to be found. The water flea (*Daphnia magna*) and the brine shrimp (*Artemia salina*) are used as fish food in aquariums and fish ponds, and the larvae of the latter are widely used as food for the larvae of larger crustaceans reared in captivity. Ostracods, of which numerous fossil and subfossil species are known, are of importance to geologists and oil prospectors.

Much damage may be done to rice paddies by burrowing crabs of various species and by the mud-eating, shrimplike *Thalassina* of Malaya. By undermining paddy embankments, they allow water to drain away, thus exposing the roots of the plants to the sun; if near the coast, salt water may thus be allowed to seep into the paddies. Tadpole shrimps (*Triops*) are often numerous in rice fields, where they stir up the fine silt in search of food, killing many of the plants. Land crabs and crayfish may damage tomato and cotton crops.

Harmful and destructive crustaceans

NATURAL HISTORY

Reproduction and life cycles. The sexes are normally, but not always, separate in crustaceans. Most barnacles have both male and female reproductive organs in one individual (hermaphroditism), and in some groups the males, when present, are much smaller than the hermaphrodites. These males attach themselves to the interior of the mantle cavity of the larger individuals and fertilize their eggs. Some of the members of the order Notostraca (tadpole shrimps) are also hermaphrodites; their ovaries contain scattered sperm-producing lobes among the developing eggs. A change of sex during the life of an individual is a regular feature in some shrimps. In *Pandalus montagui,* of the order Decapoda, some individuals begin life as males but change into functional females after about 13 months. Isopods of the genus *Rhyscotoides* show a similar change from male to female as they grow older.

Sexual dimorphism

Characteristic differences in structure or behaviour between the sexes are widespread in the Crustacea and can be extreme; the males of some groups may be so small that they are difficult to find on the much larger female. This is especially true in some of the parasitic copepods. In *Gonophysema gullmarensis* the male is found in a small pouch in the female genital tract. In many of the more advanced decapods, such as crabs and lobsters, however, the males are larger than the females and may have much larger pincers. Another example of sexual dimorphism is the possession by the male of clasping organs, which are used to hold the female during mating. Almost any appendage can be found modified for this purpose. Male appendages also can be modified to aid directly in the transfer of sperm to the female. Frequently the sperm are enclosed in a case, or spermatophore. The first and second abdominal appendages of male decapods are used to transfer spermatophores, as are the highly modified fifth legs of male copepods of the order Calanoida. These copepods can accurately place spermatophores near the openings of the female ducts. The contents of the spermatophores are extruded by a swelling of special sperm, which force out the sperm that actually fertilize the eggs.

Normal sexual reproduction involves the fusion of a sperm with an egg, but some Crustacea are parthenogenetic; that is, they produce eggs that develop without being fertilized by a sperm. Many branchiopods can do this, as can some ostracods and even more advanced crustaceans such as isopods.

Some crustaceans lay their eggs freely in the water—for example, certain copepods, such as *Calanus,* and some members of the malacostracan orders Bathynellacea, Anaspidacea, and Euphausiacea. Some euphausiids and *Nebalia* (of the malacostracan order Leptostraca) carry their eggs between the thoracic limbs. Most decapods carry their eggs attached to the abdominal appendages; special egg-containing setae secrete a cement that flows over the eggs and binds them to the setae. Most of the superorder Peracarida, some isopods, such as *Sphaeroma,* many branchiopods, the Notostraca, and the order Anostraca have a brood pouch on or behind the limbs that is often formed by the carapace. Those free-living copepods that do not cast their eggs freely into the water carry them in one or two thin-walled sacs suspended from the front of the abdomen. Some parasitic copepods produce up to six or eight egg sacs, while others produce the eggs in long strings, which may coil into a tangled mass.

Nauplius and other larvae

The most widespread and typical crustacean larva to emerge from the egg is called a nauplius (Figure 2). The main features of a nauplius are a simple, unsegmented body, three pairs of appendages (antennules, antennae, and

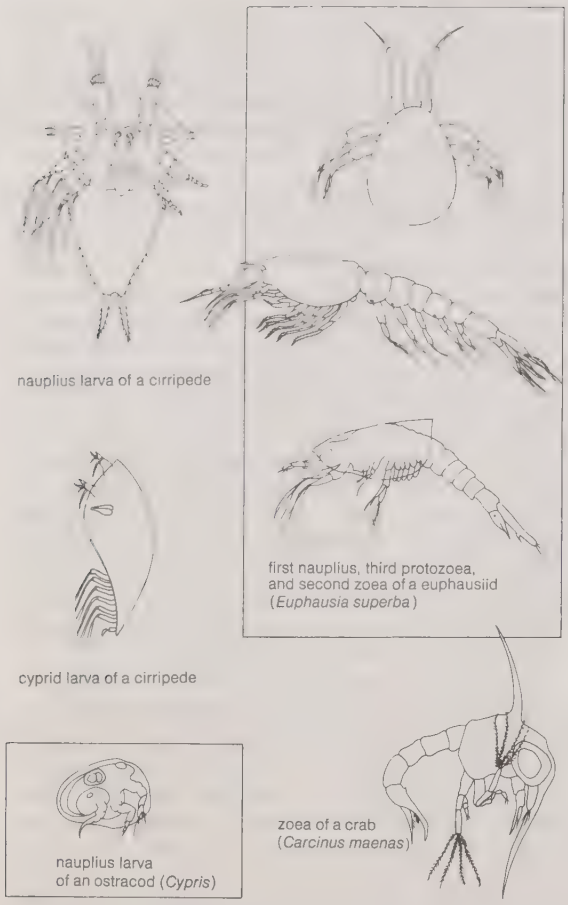

Figure 2: Crustacean larval types.

From (*Euphausia superba*) F C. Fraser, "On the Development and Distribution of the Young Stages of Krill (Euphasia superba)," *Discovery Reports XIV* (1936), Cambridge University Press, (others) W T. Calman, *A Treatise on Zoology* (1909), ed. Ray Lankester (copyright A. & C. Black Ltd., London, reprint Asher, Amsterdam, 1964)

mandibles), and a single simple nauplius eye. When the body becomes more elongated and segmented, the nauplius is called a metanauplius. Nauplius larvae are found in the cirripedes, ostracods, branchiopods, copepods, euphausiids, the decapod peneid prawns, and the subclass Thecostraca. Many of the other groups have embryonic stages like the nauplius, or they have larvae with some similarities to the nauplius.

The most primitive type of development from a nauplius is found in the anostracan fairy shrimps, where the young animal gradually adds new segments and appendages as it undergoes a long series of molts. In the free-living copepods, for example, the nauplius goes through five molts and then changes into a copepodid, which resembles the adult except that it does not have a full complement of limbs. These limbs gradually develop over another five molts; when the adult form is reached, the copepod does not molt again. The cirripede barnacle nauplius molts several times and then changes into a cyprid, which has a two-part carapace enclosing six pairs of trunk limbs. The cyprid attaches to a solid object and then metamorphoses into an adult. Larval ostracods are basically nauplii with a bivalved carapace. The euphausiid nauplius is followed by a complex series of shrimplike larvae.

The nauplius of the peneid prawns is followed by a sequence of larval forms characterized by their methods of locomotion: the metanauplius still swims with its antennae, the protozoea also uses its antennae but has developed a small carapace and some thoracic limbs, the zoea uses its thoracic limbs for swimming, and the postlarval stages use the abdominal appendages. Most decapods omit the nauplius stage and hatch as zoeae, which may be heavily ornamented with spines. The zoea of a crab changes into a megalops, which resembles a small crab with its tail extended behind it.

Some crustaceans bypass the larval stages, and the young emerging from the eggs resemble the adults. This is found in the branchiopod order Anomopoda, such as in *Daphnia,* in most isopods and amphipods, and in some decapods, including freshwater crabs and crayfish and some deep-sea and Arctic groups.

Ecology. Crustaceans play many roles in aquatic ecosystems. The planktonic forms—such as the copepod *Calanus* and the krill *Euphausia*—graze on the microscopic plants floating in the sea and in turn are eaten by fishes, seabirds, and whales. Benthic (bottom-dwelling) crustaceans are a food source for fish, and some whales feed extensively on benthic amphipods. Crabs are important predators, and the continuing struggle between them and their prey prompts the evolution of newer adaptations: the massive shells of many marine mollusks are thought to be a protective response to the predatory activities of crabs; in turn the crabs develop larger and more powerful pincers.

Elements of food chains

Crustaceans also can be parasites, and the copepods in particular parasitize other aquatic animals ranging from whales to sea anemones. The larger crustaceans are often parasitized by smaller crustaceans; for example, there are parasitic isopods that dwell in the gill chambers of decapod prawns. Freshwater crustaceans can serve as intermediate hosts for the lung fluke, *Paragonimus.*

FORM AND FUNCTION

General features. The crustacean body is difficult to characterize because the orders include a great variety of forms. The anatomy of a decapod is presented in Figure 3. The basic crustacean body consists of a number of segments, or somites. These somites sometimes are fused to form rigid areas and sometimes are free, linked to each other by flexible areas that allow some movement. Each somite has the potential for bearing a pair of appendages, although in various crustacean groups appendages are missing from certain somites. The appendages are also jointed with flexible articulations.

At the front, or anterior end, of the body there is an unsegmented, presegmental region called the acron. In most crustaceans at least four somites fuse with the acron to form the head. At the posterior end of the body there is another unsegmented region, the telson, that may bear two processes, or rami, which together form the furca. These two processes at the tail end of the body vary greatly in form; in many crustaceans they are short, but in some they may be as long as the rest of the body. The Crustacea as a whole shows great variation in the number of somites and the amount of fusion that has taken place. In the class Malacostraca, which includes the decapods, there is a consistent body plan: the trunk (which follows the head) is divided into two distinct regions, an anterior thorax of eight somites and a posterior abdomen of seven somites, although as a rule only six are evident in the adult. The reproductive ducts of a male malacostracan typically open on the last thoracic somite, and the female reproductive ducts open on the sixth thoracic segment.

The carapace is a widespread crustacean feature, arising during development as a fold from the last somite at the back of the head. It may form a broad fold extending toward the rear over the back, or dorsal surface, of the trunk, as in the notostracan tadpole shrimps, but it often

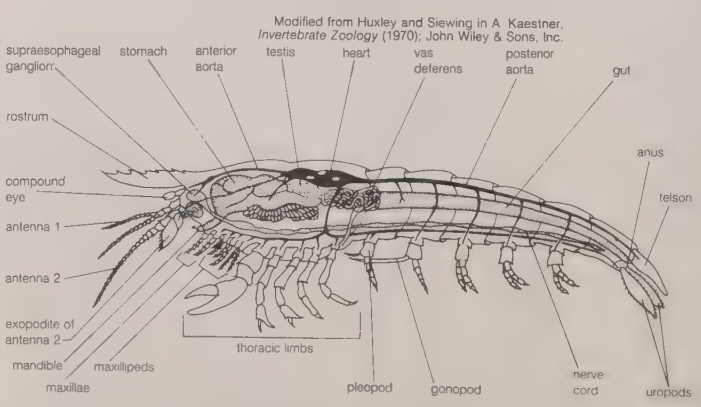

Figure 3: External and internal anatomy of a male decapod crustacean.

encloses the entire trunk, including limbs and gills. In the clam shrimps (orders Spinicaudata and Laevicaudata) and the ostracods, the carapace is split into two parts. In many decapods the carapace projects forward to form a rostrum, which is often sharply pointed and toothed. The carapace is absent from the anostracans, amphipods, isopods, and the superorder Syncarida. The barnacles attach to hard surfaces and use the highly modified carapace to form a mantle.

External features. *Appendages.* There is great diversity among the appendages of the Crustacea, but it is thought that all the different types can be derived either from the multibranched (multiramous) limb of the class Cephalocarida or from the double-branched (biramous) limb of the class Remipedia. A biramous limb (Figure 4) typically has a basal part, or protopodite, bearing two branches, an inner endopodite and an outer exopodite. The protopodite can vary greatly in its development and may have additional lobes on both its inner and outer margin, called, respectively, endites and exites. The walking legs of many malacostracans have become uniramous, losing the exopodite.

Appendages and trunk limbs

If one starts at the head of a crustacean and works toward the rear, the following appendages are encountered (some may be missing in certain species): antennae 1, or antennules; antennae 2, or antennae proper; mandibles; maxillae 1, or maxillulae; maxillae 2, or maxillae proper; and a variable number of trunk limbs. The trunk limbs all may be similar, as in the anostracans and the classes Cephalocarida and Remipedia, or they may be differentiated into distinct groups. In the copepods the first pair of trunk limbs is used in the collection of food and is called the maxillipeds. In the decapods there are three sets of paired maxillipeds. In the copepods the maxillipeds are followed by four pairs of swimming legs; a fifth pair is sometimes highly modified for reproductive purposes and is sometimes reduced to a mere vestige. Behind the maxillipeds of the decapods there are five pairs of thoracic limbs, a variable number of which may bear pincers, or chelae. In the crabs there is a single obvious pair of chelae, but in some of the prawns there may be up to three pairs of less conspicuous pincers. The abdomen of a decapod normally bears six pairs of biramous appendages, which are used in swimming in many shrimps and prawns, while in the crabs and crayfish the first two pairs in the male are modified to help in sperm transfer during mating. The last pair of abdominal limbs is frequently different from the others and is called the uropods. In shrimps and lobsters the uropods together with the telson form a tail fan.

Changes over time

The appendages often change both their form and their function during the life cycle of a crustacean. In most adults the antennules and antennae are sensory organs, but in the nauplius larva the antennae often are used for both swimming and feeding. Processes at the base of the antennae can help the mandibles push food into the mouth. The mandibles of a nauplius have two branches with a chewing or compressing lobe at the base; they also may be used for swimming. In the adult the mandible loses one of the branches, sometimes retaining the other as a palp, and the base can develop into a powerful jaw. An alternative development is found in some of the blood-sucking parasites, in which the mandibles form needlelike stylets for piercing their hosts.

Modified from R R Hessler, "Cephalocarida, Comparative Skeleton Musculature," *Connecticut Academy of Arts & Sciences Memoirs* (1964)

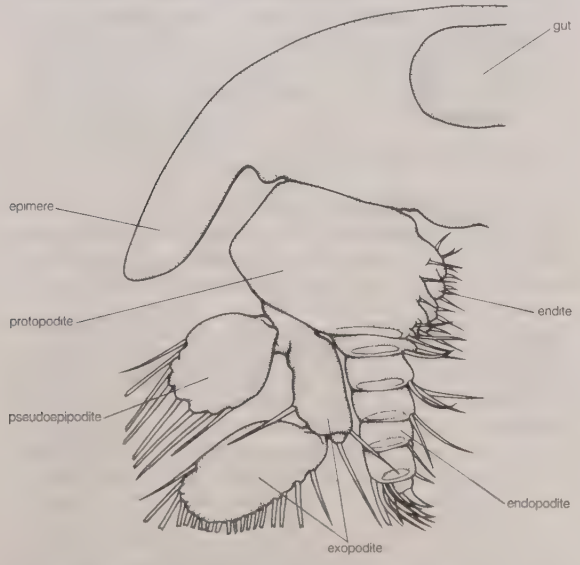

Figure 4: Thoracic leg of the cephalocarid *Hutchinsoniella macracantha*, with cross section of the left half of the trunk somite.

Exoskeleton. The outer covering of a crustacean is variously called the integument, cuticle, or exoskeleton. It protects the body and provides attachment sites for muscles. The thickness of the cuticle can vary from a thin, flexible membrane, as in some parasitic copepods, to a massive rigid shell, as in crabs. The cuticle is secreted by a single layer of cells called the epidermis. The outermost layer, or epicuticle, lacks the chitin present in the thicker innermost layers, or procuticle. The procuticle is made up of layers of chitin fibres intermeshed with proteins and, in many species, with calcium salts. Fine tubular extensions (pore canals) from the epidermis pass through the procuticle toward the surface.

Growth and molting

A typical crustacean grows in a series of stages. The hard exoskeleton prevents any increase in size except immediately after molting. The sequence of events during molting can be divided into four main stages: (1) Proecdysis, or premolt, is the period during which calcium is resorbed from the old exoskeleton into the blood. The epidermis separates from the old exoskeleton, new setae form (see below *The nervous system*), and a new exoskeleton is secreted. (2) Ecdysis, or the actual shedding of the old exoskeleton, takes place when the old exoskeleton splits along preformed lines. In the lobster it splits between the carapace and the abdomen, and the body is withdrawn through the hole, leaving the old exoskeleton almost intact. In isopods the exoskeleton is cast in two parts; the front portion may be cast several days after the hind part. Immediately after ecdysis the crustacean swells from a rapid intake of water. (3) Metecdysis, or postmolt, is the stage in which the soft cuticle gradually hardens and becomes calcified. At the end of this stage the cuticle is complete. (4) Intermolt is a period of variable duration, from a few days in small forms to a year or more in some of the large forms. Some crustaceans, after passing through a series of molts, reach a stage where they do not molt again; this is called a terminal anecdysis.

Internal features. *The nervous system.* The basic nervous system of a crustacean consists of a brain, or supraesophageal ganglion, connected to a ventral nerve cord of ganglia, or nerve centres. In primitive forms, like the anostracan fairy shrimps, the brain has nerve connections with the eyes and antennules, but the nerves to the antennae come from the connecting ring around the esophagus. In more advanced forms the antennal nerves originate in the brain. The first ventral nerve centre under the esophagus (subesophageal ganglion) is usually formed by the fusion of the ganglia from the mandibular, maxillulary, and maxillary segments, but other ganglia may be incorporated. Often there is a chain of ganglia extending the length of the trunk, but in short-bodied forms, such as barnacles and crabs, all the ventral ganglia may fuse into a single mass.

Compound eyes

The most conspicuous sense organs are the compound eyes. In a typical decapod each eye consists of several hundred tubular units radiating from the end of an optic nerve. Each of these units is a miniature eye, with a central optical tract isolated from the others by two groups of pigment cells. These pigment cells can expand and contract to cover varying amounts of each tubular eye, enabling the eyes to be used over a range of light intensities. The image obtained with such an eye is a mosaic, but there is evidence from the behaviour of the advanced crabs that they perceive a good image and that they can detect small movements. Single median eyes are also found in crustaceans, particularly in the nauplius larvae. Only three or four simple units are usually found in the nauplius eye,

which is innervated by a median nerve from the forebrain. The median eye also may persist through to the adult stage. In the copepods the median eye is the only eye, but in some groups it may persist even when the compound eyes have developed. In the Notostraca, the name *Triops* draws attention to this phenomenon, but it is also known in other groups, including some of the decapods.

Setae

Other stimuli are detected by means of various setae, or hairlike processes, that project from the surface of the exoskeleton and are connected to a nerve supply. Some setae are tactile, detecting contact and movement when deflected. Other setae are used in association with statocysts. Statocysts are paired organs, located at the base of the antennules in decapods or at the base of the uropods in mysids, that enable the crustacean to orient itself with respect to gravity. Each statocyst is a rounded sac containing one or more small granules, called statoliths, that rest on numerous small setae. Any change in orientation causes the statoliths to impinge on the setae at a different angle, and this information is relayed to the brain so that corrective action can be taken. Finally, other setae are chemosensory; they detect a wide range of chemical substances. Such setae are usually tubular and thin-walled, sometimes with a small pore at the top. They are especially abundant on the antennules and mouthparts.

The digestive system. The gut is usually direct in its passage through the body and is coiled in only a few water fleas of the order Anomopoda. The foregut shows the greatest range of structure; in some it is a simple tube; while in decapods it reaches great complexity in having a

Gastric mill

structure called the gastric mill. This consists of a series of calcified plates, or ossicles, that are moved against each other by powerful muscles, making an efficient grinding apparatus. The junction between the mill and the midgut is guarded by a filter of setae, which prevent large particles from passing into the midgut. The structure of the midgut is also variable but generally has one or more diverticula, or pouches, which are involved in various digestive processes. These diverticula may be simple, as in *Daphnia,* or complex and glandular, as in the decapods. The hindgut is usually relatively short and lined with cuticle. The exit is controlled by a muscular anus, which in some forms had dilator muscles that control anal swallowing.

The excretory system. Two different excretory organs are found in the crustaceans: the antennal gland and the maxillary gland. Both have the same basic structure: an end sac and a convoluted duct that may expand into a bladder before opening to the outside. In most adult crustaceans only one or the other gland functions. The functional gland may change during the life cycle.

The main function of the antennal and maxillary glands is the regulation of ionic balance. The total balance of salts and water is also controlled in part by the gut, which can absorb both. The antennal gland also has been shown to reabsorb glucose. Most crustaceans excrete the end product of nitrogen metabolism, in the form of ammonia, through the gills. Some of the more terrestrial forms produce urea or uric acid, which may be stored in special large cells near the bases of the legs.

The respiratory system. Many of the smaller crustaceans have no special respiratory organs. Gas exchange takes place through the entire thin integument. The inner wall of the carapace, facing the trunk, is often rich with blood vessels and may in many groups be the only respiratory organ. Gills, when present, are formed by modifications of parts of appendages, most often the epipodites. These thin-walled, lamellate structures are present on some or all of the thoracic appendages in cephalocarids, fairy shrimps, and many malacostracans. In mantis shrimps (order Stomatopoda), for example, gills are found on the exopodites of the pleopods. In euphausiids the single series of branched epipodial gills are fully exposed. In decapods the gills, protected by the overhanging carapace, are arranged in three series at or near the limb bases. As an adaptation to aerial respiration, the branchial chambers are greatly enlarged in certain land crabs and serve as lungs, the inner membrane being richly supplied with blood vessels. In isopods the respiratory function has been taken over by the abdominal appendages; either both rami or the endopodite become thin and flattened. Most sow bugs and pill bugs have, in addition, trachea-like infoldings in some of the exopodites.

The circulatory system. As in other arthropods, the blood flows in sinuses, or channels, without definite walls. Cirripedes and many ostracods and copepods have no heart, the blood being kept in motion by either a blood pump or rhythmic movements of the body, gut, or appendages. When present, the heart lies in a blood sinus, or pericardium, with which it communicates by paired valvular openings, or ostia. In the more primitive crustaceans, such as fairy shrimps or stomatopods, the heart is a long tube, with spiral muscles in its wall, and extends almost the entire length of the trunk; there is a pair of ostia in each somite except the last. In more-advanced crustaceans, however, the heart may be shortened, and the number of ostia may be reduced to three pairs or less. The position of the heart depends on that of the respiratory organs; it usually lies in the thorax or cephalothorax but is mainly in the abdomen of isopods. Malacostracans have a well-developed system of elastic-walled arteries, including an anterior and usually a posterior aorta.

The heart

The red respiratory, or oxygen-carrying, pigment hemoglobin has been observed in the blood of the Branchiopoda and in other classes except Malacostraca. Hemocyanin is the respiratory pigment in the malacostracan decapods and stomatopods.

Hormones. Hormones are substances produced in one part of the body that act on cells in some other part of the body. The secretory system that produces these substances is known as the endocrine system. Most of the information about crustacean hormones has been obtained from studies on the decapods, but a fair amount is also known about the hormones of the isopods and amphipods.

X-organ–sinus-gland complex

The X-organ–sinus-gland complex is located in the eyestalk. The X-organ passes its secretions to the sinus gland, which acts as a release centre into the blood. Hormones liberated from the sinus gland have been shown to influence molting, gonad development, water balance, blood glucose, and the expansion and contraction of pigment cells both in the general body and in the retina of the eye. The Y-organs lie in the maxillary segment of decapods and are the source of molting hormones, or ecdysteroids, which promote molting and interact with molt-inhibiting hormones from the X-organ.

The brain and thoracic nerve centres produce hormones that promote the development of the sex organs. In addition, certain glands attached to the male reproductive ducts control the development of the male reproductive system; their removal from a young male will cause it to develop into a female. The female ovary also acts as an endocrine organ; its endocrine secretions control the development of the female reproductive system. The brood pouch in both amphipods and isopods also develops under the influence of ovarian secretions. A hormonal system controls the beating of the heart. Nerves from the thoracic centres end in fine secretory fibres in the membrane enclosing the space around the heart (pericardium) and secrete substances that typically produce an increase in both frequency and amplitude of the heartbeat.

EVOLUTION AND PALEONTOLOGY

There are two approaches to the study of crustacean evolution. The first involves the interpretation of the evidence from comparative anatomy. The second involves a consideration of the fossil record.

Various attempts have been made to construct a hypothetical ancestral crustacean from which it would be possible to derive all the others. The prerequisites for such an ancestor seem to be an elongated body, two pairs of appendages in front of the mouth, a pair of mandibles behind the mouth, and numerous trunk segments with appendages that form a continuous series of similar structure. Before the discovery of the class Cephalocarida, some of the primitive members of the class Branchiopoda, such as the orders Anostraca and Notostraca, were thought to show what such an ancestor might have been like. The Cephalocarida, in having trunk limbs with a jointed inner branch and a platelike outer branch, further showed a pos-

sible original structure from which almost any crustacean limb could have been derived. The discovery of the class Remipedia, with a long series of similar trunk limbs, has reopened the question of the original form of the trunk limb in the ancestral crustacean. The Remipedia are undoubtedly primitive, but they do have some adaptations as cave dwellers. The question is still open as to whether the carapace is a primitive crustacean structure or whether it is a feature that has evolved independently in each group.

The fossil record, although fairly rich, has not solved any of the questions about the early evolution of the Crustacea. The earliest of the definite fossil crustaceans are ostracods, a relatively specialized group. There are also indications from the Burgess shales of the Cambrian period (570 to 505 million years ago) that many features of crustacean organization had already evolved by this time. It is only when the later, more highly evolved class Malacostraca is studied that there is good agreement between comparative anatomy and the fossil record. The decapod *Palaeopalaemon,* a shrimplike form, occurs in the Devonian (408 to 360 million years ago), crayfish occur in the Late Permian (258 to 245 million years ago), and allies of the hermit crabs (Anomura) are found in the Jurassic (208 to 144 million years ago). The true crabs (Brachyura), which represent one of the pinnacles of crustacean evolution, do not occur until the beginning of the Cretaceous (144 to 66.5 million years ago).

CLASSIFICATION

Distinguishing taxonomic features. In classifying the Crustacea, a variety of characters are important: the form and extent of the carapace, if present; the number of trunk somites, or segments, and how many fuse with the head or with the telson; the number and degree of specialization of the trunk limbs; the presence or absence of paired eyes and of a caudal furca—*i.e.,* a forked-tail process; and the position and kind of respiratory organs. The position of the genital openings, the mode of attachment of the eggs to the female, and the stage at which the first larva hatches may also be significant. Parasitic and sedentary forms may differ markedly as adults from free-living species.

(I.G./J.Gre.)

Annotated classification. The following classification is based largely on that given in D.E. Bliss, *The Biology of Crustacea,* vol. 1, (1982) but has been modified to take account of advances made since that date. Groups marked with a dagger (†) are extinct and known only from fossils.

SUBPHYLUM CRUSTACEA

Two pairs of sensory appendages in front of mouth, and 3 pairs of jaws behind mouth; some parasitic and lack all appendages when adult; mostly aquatic; about 39,000 species known.

Class Cephalocarida (horseshoe shrimps)

Holocene; primitive; blind; head shield without carapace; maxilla and all trunk limbs alike, with jointed inner branch and leaflike outer branches; abdominal segments without limbs; telson and furca present; length about 3 mm; marine, intertidal down to 300 m; few known species.

Class Branchiopoda

Early Devonian to present; limbs usually leaflike; maxillae reduced; eyes sometimes stalked, usually sessile (unstalked), often fused to form a single large median eye; nauplius, but some with direct development; predominantly freshwater, some marine, and some in strong inland brines; about 900 species.

†Class Enantiopoda

Carboniferous; single fossil, *Tesnusocaris.*

Class Remipedia

Holocene; body elongated; more than 30 segments, each with biramous appendages projecting sideways; antennules biramous; maxillules, maxillae, and maxillipeds uniramous and grasping; marine cave dwellers; few species.

Class Maxillopoda

Five pairs of head appendages; single, simple, median eye; antennules uniramous; maxillae usually present; up to 11 trunk segments.

Subclass Thecostraca

Bivalved carapace of cypris larva forms an enveloping mantle in the adult; parasitic forms recognizable only by larval stages.

Order Ascothoracica. Cretaceous to present; parasites on sea anemones and echinoderms; body typically enclosed in a bivalved carapace; some with segmented abdomen and caudal furca; others distorted by outgrowths of the gut and ovary, giving a bushlike appearance; males dwarfed, living in mantle cavities of females; marine; about 50 species.

Order Rhizocephala. Parasites on other crustaceans, mostly decapods; larvae typical nauplii and cyprids; adults ramify inside hosts and produce 1 or more reproductive bodies outside the host; marine; about 230 species.

Order (*Subclass*) *Cirripedia* (barnacles). Late Silurian to present; sedentary; 6 pairs of trunk limbs (cirri); larvae free-swimming; sessile adults with carapace developed into a mantle.

Subclass Tantulocarida

Holocene; eggs give rise to a tantulus larva with head shield and 6 pairs of thoracic limbs; adult females form large dorsal trunk sac between head shield and trunk, often losing the trunk; males with 6 pairs of trunk limbs; parasites on other crustaceans; marine; about 10 species.

Subclass Ostracoda (mussel or seed shrimps)

Cambrian to present; body short; bivalved carapace encloses trunk and limbs; living forms have up to 7 pairs of appendages; most fossils known only from shells (carapaces); marine, freshwater, and some terrestrial; more than 2,000 living species worldwide.

†*Order Bradoriida.* Cambrian to Ordovician.

†*Order Phosphatocopida.* Cambrian; remarkable fossils with up to 9 pairs of well-preserved appendages.

†*Order Leperditicopida.* Cambrian to Devonian.

†*Order Beyrichicopida.* Silurian to Carboniferous.

Order Myodocopida. Silurian to present; antennal notch in shell; 5 pairs of postoral appendages; maxilla with a large respiratory plate; eyes usually present; marine.

Order Halocyprida. Silurian to present; 5 pairs of postoral appendages; maxilla leglike; no eyes; marine.

Order Cladocopida. Silurian to present; only 3 pairs of postoral appendages; marine.

Order Platycopida. Ordovician to present; antennae biramous; 4 pairs of postoral limbs; marine.

Order Podocopida. Ordovician to present; antennae uniramous; 5 pairs of postoral appendages; marine, freshwater, and terrestrial.

Subclass Branchiura

Order Arguloida (fish lice). Wide, flat carapace; paired compound eyes; unsegmented abdomen; 4 pairs of trunk limbs; fish parasites; capable of free swimming; mostly freshwater but some marine; about 150 species.

†*Subclass Skaracarida*

Late Cambrian; 12 trunk segments; no thoracic appendages apart from maxillipeds.

Subclass Copepoda

Miocene to present; no carapace; no compound eyes; 1 or more trunk segments fused to head; typically 6 pairs of thoracic limbs; no abdominal limbs; larva usually a nauplius; free-living and parasitic; worldwide; marine, freshwater, and some semiterrestrial; at least 10,000 species.

Order Calanoida. Antennules long, usually held stiffly at right angles to the length of the body; heart present; thorax articulates with a much narrower abdomen; fifth leg biramous; worldwide; marine and freshwater; mostly planktonic.

Order Misophrioida. Carapace-like extension from the head covers the first segment bearing a swimming leg; heart present in some; no eyes; antennule with up to 27 segments; fifth leg biramous; marine.

Order Mormonilloida. Antennule with 3 or 4 long segments and long setae; fifth leg absent; marine.

Order Harpacticoida. Antennules short; abdomen not markedly narrower than the thorax; articulation between thoracic segments 5 and 6; mostly benthic, some tunnel in the fronds of seaweeds; usually 1 egg sac but some with 2; marine and freshwater, with some semiterrestrial on damp forest floors.

Order Cyclopoida. Antennules medium length; thorax wider than abdomen; articulation between thoracic segments 5 and 6; mandibles with biting or chewing processes; eggs normally carried in 2 egg sacs; fifth leg uniramous; marine and freshwater.

Order Poecilostomatoida. Parasites and commensals of fish and invertebrates; mouth not tubelike or suckerlike; mandibles reduced; adult segmentation often reduced or lost; mostly marine, few freshwater.

Order Siphonostomatoida. Mouth tubelike or forms a sucker with styletlike mandibles; adult segmentation reduced or lost; parasites and commensals on fish and invertebrates; mostly marine, some freshwater.

Order Monstrilloida. Parasites on marine worms and mollusks; adults free-swimming; lack mouthparts and gut; biramous swimming legs.

Subclass Mystacocarida (mustache shrimps)

Elongated; blind forms living in spaces between sand grains;

antennules uniramous; antennae and mandibles biramous with long branches extending sideways; trunk limbs vestigial but caudal rami well-developed and pincerlike; marine; about 9 species.

Class Malacostraca

Cambrian to present; typically with compound eyes, stalked or sessile; 8 thoracic and 6 abdominal segments, each potentially capable of bearing a pair of appendages; about 22,000 species.

Subclass Phyllocarida

Early Cambrian to present.

†*Order Archaeostraca.* Devonian to Triassic.

†*Order Hoplostraca.* Carboniferous.

Order Leptostraca. Permian to present; bivalved carapace encloses 8 pairs of leaflike limbs; movable rostrum; telson with caudal rami; marine; about 10 species.

Subclass Hoplocarida

Carboniferous to present.

Order Stomatopoda (mantis shrimps). Jurassic to present; eyes stalked; 2 movable segments in head; carapace leaves 4 thoracic segments uncovered; second thoracic limbs massive; marine; about 350 species.

†*Order Palaeostomatopoda.* Carboniferous.

†*Order Aeschronectida.* Carboniferous.

Subclass Eumalacostraca

Late Devonian to Holocene; carapace (when present) not bivalved; rostrum fixed; first antenna 2-branched; thoracic legs with slender, many-segmented outer branch and stout, 7-segmented inner branch, often pincerlike, used in walking or food-gathering; 6 (rarely 7) abdominal segments, with pleopods and terminal uropods.

Superorder Syncarida. Carboniferous to present; no carapace.

†*Order Palaeocaridacea.* Carboniferous to Permian; first thoracic segment not fused to head; abdominal pleopods 2-branched, flaplike; 4 families.

Order Anaspidacea. Permian to present; with or without eyes; antennules biramous; abdominal appendages well-developed; telson without a furca; South Australia and Tasmania; freshwater; about 8 species.

Order Stygocaridacea. Blind, elongated forms with a small rostrum; first thoracic segment fused to head but sixth abdominal segment free; furca present; abdominal appendages reduced or absent; South America and New Zealand; freshwater, in spaces between sand grains; about 5 species.

Order Bathynellacea. Blind, elongated forms, without a rostrum; first thoracic segment not fused to head but sixth abdominal segment fused with telson; antennules uniramous; worldwide; freshwater, in spaces between sand grains; about 100 species.

Superorder Peracarida. Females with a ventral brood pouch formed by plates at the bases of some of the thoracic limbs; development direct, with offspring resembling adults.

Order Mysidacea (opossum shrimps). Triassic to present; carapace well-developed, covering most of thorax; 3–30 mm, with a few much larger; worldwide; mainly marine but some in brackish and fresh water; about 780 species.

Order Cumacea. Permian to present; head and carapace much wider than trunk; uropods long and rodlike; 1–35 mm; marine; about 800 species.

Order Spelaeogriphacea. Holocene; carapace short, fused to first and covering part of second thoracic segment; 4 pairs of well-developed abdominal appendages; about 8 mm; cave-dwelling; South Africa; freshwater; 1 species.

Order Mictacea. Holocene; no functional eyes; carapace forms small lateral folds covering bases of mouthparts and maxillipeds; all trunk segments free; antennules biramous; thoracic limbs with exopods; abdominal appendages reduced, uniramous; 2.7–3.5 mm; deep-sea or in marine caves; 2 species.

Order Tanaidacea. Permian to present; carapace short, fused to first 2 thoracic segments; second pair of thoracic limbs usually with pincers; abdomen short, usually with 5 pairs of biramous appendages; 2–25 mm; mainly marine; about 500 species.

Order Isopoda (pill bugs, wood lice, sea slaters). Carboniferous to present; eyes sessile; no carapace; abdominal appendages flattened and respiratory; thoracic limbs without exopods; some parasites highly modified as adults; most species 5–30 mm but some up to 270 mm; worldwide; marine, freshwater, and terrestrial; about 4,000 species.

Order Amphipoda (beach hoppers, scuds, well shrimps). Eocene to present; eyes sessile; no carapace; thoracic limbs have respiratory plates at base; few parasites; most 5–50 mm but up to 140 mm; worldwide; mainly marine but also numerous in fresh water; about 6,000 species.

Superorder Eucarida. Carapace large, fused dorsally to all thoracic segments; eyes stalked; development usually involves larval forms but is sometimes direct.

Order Euphausiacea (krill). Holocene; carapace does not cover gills; thoracic limbs with 2 well-developed branches; eggs usually shed freely; first larva a nauplius; 6–81 mm; worldwide; marine; about 85 species.

Order Amphionidacea. Holocene; carapace large; mandible and maxillule vestigial; thoracic limbs with small outer branch; ventral brood pouch formed by large forwardly projecting first abdominal appendages; 2–3 cm; worldwide; marine, pelagic; 1 species.

Order Decapoda (shrimps, prawns, lobsters, crayfish, crabs). Devonian to present; carapace large, enclosing gills; first 3 pairs of thoracic appendages modified for feeding (maxillipeds); eggs often attached to abdominal appendages; worldwide; mostly marine but also freshwater and a few terrestrial; about 10,000 species.

Superorder Pancarida

Order Thermosbaenacea. Holocene; eyes reduced or absent; brood pouch formed from dorsal extension of carapace; length about 4 mm; fresh and brackish water, some in warm springs; about 9 species.

Critical appraisal. There is no universal agreement on the classification of the Crustacea and even less agreement on the interrelationships among the various groups. Alternative classifications of the classes Branchiopoda and Malacostraca are discussed below. Some authorities, such as the author of the Cirripedes below, rank the cirripedes as a subclass. There is also some disagreement about the limits of the class Maxillopoda. Some would include the class Cephalocarida, others would exclude the class Ostracoda, and yet others do not regard the Maxillopoda as a valid group and would raise the maxilloped subclasses Copepoda and Ostracoda to separate classes. Some of the parasitic forms are sometimes separated and ranked as separate orders.

MAJOR CRUSTACEAN GROUPS

Branchiopods (fairy shrimps, tadpole shrimps, brine shrimps, and water fleas)

Branchiopods are generally regarded as primitive crustaceans. Their long fossil record dates back to the Devonian period (408 to 360 million years ago). Although certain members of the group, such as the order Anostraca, are mainly confined to temporary pools, the water flea, order Anomopoda, is so successful that there are few fresh waters in the world without one or more species of anomopod.

GENERAL FEATURES

Size range and diversity of structure. The smallest branchiopods are found among the anomopods, where some species are only 0.25 millimetre (0.01 inch) long. The largest living branchiopod is *Branchinecta gigas*, a fairy shrimp that reaches a length of 10 centimetres (3.9 inches). Some members of the fossil order Kazacharthra also grew to a length of 10 centimetres.

The class Branchiopoda is divided into 10 orders, two of which are extinct and known only through the fossil record. The eight living orders show a great diversity of form. In the Laevicaudata, for example, the number of trunk segments remains constant; there are 12 pairs of trunk limbs in the female and 10 pairs in the male. In the Spinicaudata, however, the number of paired trunk segments varies among its members from 12 up to 32 in some species. A carapace is present in the orders Ctenopoda and Anomopoda, but it encloses only the trunk, leaving the head free. In the orders Onychopoda and Haplopoda the carapace does not enclose the trunk limbs but forms a brood pouch on the dorsal surface. The anostracans (fairy shrimps and brine shrimps) lack a carapace and have stalked eyes, in contrast to the other living group, whose eyes are set into the head.

The two fossil groups as well differ markedly from each other. The order Lipostraca lacked a carapace and had 13 pairs of trunk limbs and a pair of large antennae, which appear to have been used in swimming. The order Kazacharthra had a well-developed carapace and six pairs of large thoracic limbs. The main structural feature linking these diverse forms, both living and fossil, is the flattened, or paddlelike, trunk limb, which often but not always is used in filter feeding. In the orders Onychopoda and Haplopoda even this feature is modified, and the trunk limbs have become specialized for grasping prey.

Distribution and abundance. Branchiopods are found worldwide in fresh waters. The anostracans, notostracans, and the orders Laevicaudata and Spinicaudata are particularly characteristic of temporary waters, where they survive dry periods as resting eggs. The anostracan *Branchinecta paludosa* and the notostracan *Lepidurus arcticus* are regularly found in small pools of the Arctic tundra regions. These pools are temporary in the sense that they freeze solid in winter. A few species in these groups are found in permanent waters.

The ctenopods and anomopods play an important role in fresh waters throughout the world, both in the open waters of large lakes and in the shallower plant-rich zones around the margins of ponds and lakes. Their diet consists to a large extent of algae and bacteria, and in turn they are important as food for fish. A few species of the orders Ctenopoda and Onychopoda are found in the sea, and the anostracan brine shrimp *Artemia* is often abundant in inland saline waters. The immature forms of *Artemia* are used as food for the young of various marine fishes commercially reared in artificial conditions.

Marine and freshwater habitats

NATURAL HISTORY

Reproduction and life cycles. A typical branchiopod begins its life cycle as a nauplius larva (Figure 2), which has a simple undivided body and three pairs of appendages: antennules, antennae, and mandibles. The antennae are used for swimming. As the nauplius feeds and grows, it gradually changes into the adult form—the body becomes segmented, or jointed, and additional limbs develop. In adult anostracans and notostracans the antennae lose their swimming function, but in adults of the other six orders they remain large and functional. The spinicaudate *Cyclestheria* lays its eggs in the space between the trunk and the carapace. These eggs develop rapidly into miniatures of the adult, skipping the larval stages. A similar mode of reproduction is found in the ctenopods, anomopods, and onychopods.

Branchiopods mature rapidly. A small cladoceran can lay eggs in the warm water of a temporary desert pool after two days. In temperate latitudes, a cladoceran may mature in less than a week during a warm summer.

The sexual arrangement in some branchiopods is that of separate males and females. Others are modified so that their eggs develop without fertilization (parthenogenesis). Some branchiopods have both male and female reproductive structures in one individual.

Among the branchiopods the anomopods show the greatest variety of reproductive habits. Under favourable conditions the eggs are laid in a brood pouch between the carapace and the trunk. There they develop rapidly and, after about two days, hatch as females, which in turn lay eggs that give rise to more females. No males are necessary for this process. When food is scarce or when there is a sudden temperature change, some of the eggs develop into males, and some of the females begin producing eggs that must be fertilized by sperm from the males. These fertilized eggs are remarkably resistant to unfavourable environmental conditions; even if frozen or dried, they will hatch when returned to favourable conditions. Many anomopods survive the winter as fertilized eggs; species that dwell in temporary pools lay such eggs to survive periods of drought. Certain Arctic or alpine anomopods, such as *Daphnia middendorffiana,* produce resistant eggs that do not require fertilization. The resistant, or dormant, fertilized eggs normally hatch in the following spring, giving rise to the usual miniature adult females. In *Leptodora* the resting egg hatches into a nauplius larva, although the rapidly developing eggs produced in the summer give rise to miniature females.

Resistance of eggs to environmental hazards

Members of the other branchiopod orders also can produce dormant, fertilized eggs. Many desert-pool species produce only resting eggs; they must abbreviate their life cycles to coincide with the brief period of favourable conditions, and their eggs must be capable of remaining dry for long periods, sometimes several years.

Ecology. Some species of *Daphnia* in temperate lakes show a remarkable seasonal change in form. In the winter the females have rounded heads, but the females of generations in late spring and summer have pointed heads. High temperature and water turbulence favour the development of a pointed head. The most plausible explanation seems to be related to predation by fish. The feeding activity of plankton-eating fish decreases in winter and increases rapidly in the spring and summer. The fish select the large *Daphnia,* the most conspicuous parts of which are the eye and the carapace with its enclosed limbs and eggs. When the head becomes pointed and enlarged, the size of the carapace is reduced, and the eye is often smaller. Thus, there is an overall decrease in conspicuousness that occurs in the summer forms.

Food gathering

The trunk limbs of all branchiopods are used to gather food. Filters formed by setae, or fine hairs, separate the food particles from the water, and an elaborate mechanism shifts food from the filters to the mouth. The filters enable branchiopods to collect material as small as bacteria for food. The ability to utilize bacteria is important in cleansing water in reservoirs, where *Daphnia* is often abundant.

The notostracans *Triops* and *Lepidurus* can collect small particles, but they can also act as predators. *Lepidurus arcticus* has been observed feeding on another Arctic branchiopod, the anostracan *Branchinecta paludosa,* which often lives in the same tundra pools. Sometimes a species changes its feeding habits with age. The large fairy shrimp *Branchinecta ferox* feeds on small particles when young but becomes a predator when mature.

Locomotion. Notostracans and anostracans swim with their trunk limbs, which beat in a rhythm so that jets of water are forced out sideways and backward from the spaces between the limbs to drive the animal ahead. Some anostracans, such as *Chirocephalus,* have a complex system of flaps and muscles in the trunk limbs, and they modify the limb movement in order to hover in one position for long periods. The other six orders swim by means of their antennae, which have two branches bearing featherlike setae that increase the effective area of the antenna. The orders Spinicaudata and Laevicaudata are slow, clumsy swimmers, and they are highly vulnerable to predation by fish; thus, they are most commonly found in temporary pools, where fish are absent. The anomopods, although smaller, are much livelier swimmers.

Responses to light. The most notable behavioral responses of branchiopods are in relation to light. The Anostraca are remarkable in showing a ventral light response: when light is directed from above, they turn their ventral surface toward the light. If they are artificially lit from below and not from above, they turn over. In the anomopods the response to light is complex and varies with the colour of the light. In red light, *Daphnia* maintains its position in the water by a hop-and-drop type of swimming. In blue light, it swims more rapidly in a horizontal direction. These two methods of swimming are related to the presence of food. When foods such as small green algae are present in the water, they absorb most of the blue light, and the light that penetrates is mainly red. Stationary swimming in response to this red light is advantageous to *Daphnia,* and it maintains its position. In the absence of food such as green algae, more blue light is present in the water. *Daphnia* is stimulated in response to this blue light to swim horizontally and to search a wider area. If *Daphnia* is starved and kept in red light, however, it eventually swims horizontally; *i.e.,* starvation blocks out the normal response to red light.

FORM AND FUNCTION

External features. The fundamental structure of the Branchiopoda is related to their methods of feeding. In

General features

most species this involves a series of limbs acting together to filter, scrape, or otherwise gather food particles into a ventral food groove and transport them to the mouth. In the elongated forms, such as the anostracans, the segmentation of the trunk is simple and obvious, but in the short-bodied forms, such as the anomopods and onychopods, the trunk is much compressed and the segmentation is obscured. The exoskeleton of the branchiopods is generally thin and flexible, although in the notostracans it can be quite rigid in some parts. The crushing or biting parts of the mandibles are usually the thickest and strongest. The trunk limbs often have a complex intrinsic musculature, which enables the various parts of the limb to be moved relative to each other. Extrinsic muscles, having their origins within the trunk, operate at the bases of the limbs and are responsible for movements of the whole limb. The primitive branchiopod limb can be thought of as a multipurpose flap serving for locomotion, feeding, and respiration.

Internal features. *The circulatory system.* The heart of a branchiopod is often visible in the intact animal. In *Daphnia* (Figure 5) the heart is short and almost spherical, with two inlet holes, or ostia, and a single anterior opening. In the more elongated forms, such as the anostracans, the heart is longer, with a pair of ostia in each trunk segment except the first and last. In the notostracans the heart has 11 pairs of ostia, while the spinicaudates have four pairs and the laevicaudates three pairs. In all branchiopods the heart discharges blood into an open body cavity, or hemocoel, without any definite vessels. In spite of this open system the blood follows a fairly definite course around the body, a good proportion passing through the trunk limbs before returning to the heart.

Blood

The blood of branchiopods is unusual among crustaceans in containing the red respiratory pigment hemoglobin dissolved in the plasma. The concentration of hemoglobin in branchiopod blood varies inversely with the oxygen content of the surrounding water: when little oxygen is in the water, the blood contains a large quantity of hemoglobin and is bright red.

The nervous system. The nervous system of the branchiopods consists of a cerebral ganglion, or brain, connected to two chains of ventral ganglia, which run along the trunk, underneath the gut. Nerves develop from these ganglia to the various mouthparts and limbs. In the anostracans the two chains are cross-connected in each segment so that the system resembles a ladder. In the short-bodied forms, such as the anomopods and onychopods, the ventral nervous system is condensed into a single mass. The most conspicuous sense organs are the eyes. In the anostracans the eyes are on movable stalks, while in the notostracans the paired eyes lie close together on top of the head. In the other living branchiopods the eyes join together to form a single more or less spherical eye in the middle of the head. All branchiopod eyes are provided with muscles and show rapid trembling movements thought to be part of a scanning process that gives more information about the surroundings than could be gained with a stationary eye. Other sense organs in branchiopods are used mainly as organs of touch (mechanoreception) or taste (chemoreception). These sense organs take the form of bristles connected with nerves at their base, and those concerned with taste are often thin-walled and tubular in form. The notostracans in particular are richly endowed with both sorts of receptors on their trunk limbs; they help in sorting the edible from the inedible as the animal grubs about in the mud at the bottom of a pool.

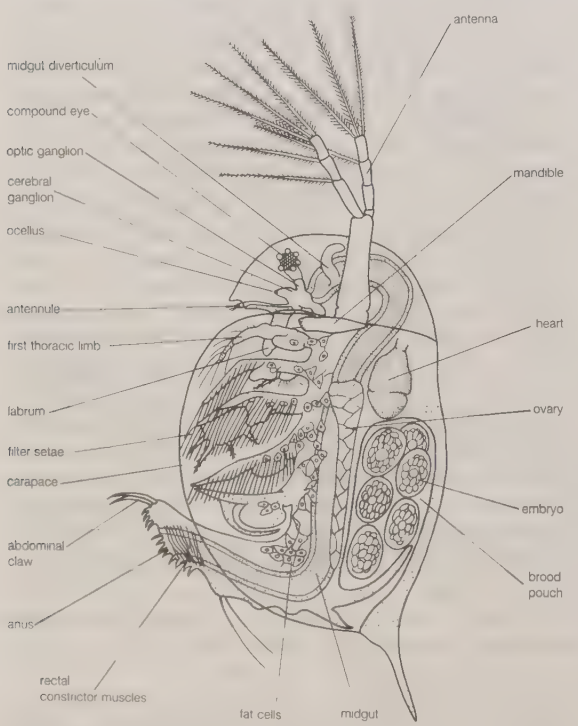

Figure 5: *Daphnia magna*, lateral view of adult female.

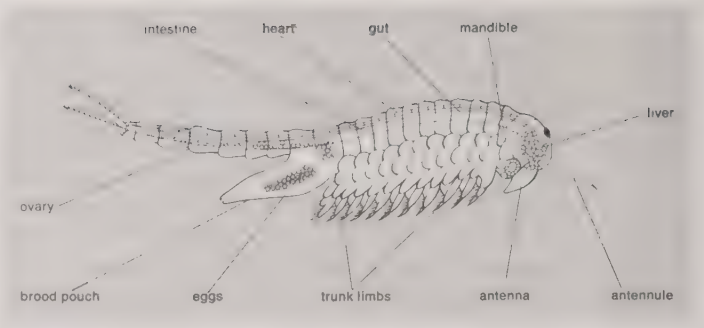

Figure 6: *Chirocephalus diaphanus*, an anostracan branchiopod.

From L. Borradaile and F. Potts, *The Invertebrata*, published by Cambridge University Press

The digestive system. The digestive system of the branchiopods shows considerable variation. In most groups the esophagus is narrow and has muscles which can dilate and others which can contract so that food can be pushed rapidly into the midgut. In many branchiopods the midgut is a simple tube with a pair of blind sacs, or diverticula. These diverticula may be simple extensions from the gut, or they may be complexly branched as in the notostracans and the spinicaudates. Some anomopods of the family Chydoridae have coiled midguts and may also have a single posterior diverticulum. One phenomenon shown by many branchiopods is anal swallowing. Water is taken in through the anus and is thought to act like an enema in clearing unwanted material from the hindgut.

The midgut

The excretory system. The excretory organ in the branchiopods is the maxillary, or shell, gland, so called because loops of the excretory duct can be seen in the wall of the carapace. In the nauplius larva the excretory function is performed by a gland opening on the antennae, but this degenerates as the animal grows and the maxillary gland takes over. Some excretion also can occur through the wall of the gut, which transfers substances from the blood into the gut lumen, from which it passes to the outside.

Most of the branchiopods have thin cuticles so that a certain amount of respiratory exchange can take place over the general body surface. The trunk limbs of most groups are flattened and leaflike, and on their outer edges they bear thin-walled lobes that can function like gills. The continuous movements of the trunk limbs of an anostracan, for instance, ensure a constant flow of water over these lobes. The lobes on the trunk limbs also play a part in ionic regulation, a process that controls the concentration and composition of the salts in the body fluids.

Hormones. There is good evidence of cyclic secretion of substances in the brain, which appears to be related to the control of molting and reproduction.

EVOLUTION AND PALEONTOLOGY

The Branchiopoda originated in pre-Devonian times, for in the Devonian period two distinct orders are evident: the Lipostraca and the Spinicaudata. The Lipostraca contains only *Lepidocaris rhyniensis*, from the Rhynie cherts of

Scotland. This minute branchiopod is preserved so well that fine details of its limbs can be seen. Its structure is better known than that of any other fossil crustacean. It is even possible to deduce its method of feeding. The first three pairs of trunk limbs could have scraped material from the surfaces of plants or stones, and the food could then be transported forward to the mouth by a series of setae near the bases of the limbs. The trunk limbs lying behind the first three were two-branched and could have been used for swimming. Fossil members of the Spinicaudata are also known from the Devonian period, but their limb structure is not known in the detail available for *Lepidocaris;* many were preserved only as carapaces. The Laevicaudata extends back as far as the Early Cretaceous epoch (144 to 97.5 million years ago).

The Kazacharthra were much larger than *Lepidocaris* and occur later in the fossil record, being found in the Early Jurassic epoch (208 to 187 million years ago). They had elongated bodies with more than 40 body segments, a large carapace, and six pairs of complex flattened limbs.

At various times some of the fossils from the Burgess shales of the Cambrian period have been allocated to the Branchiopoda, but none of these has been generally accepted. Some fossils from the Cambrian period of Sweden, however, show features similar to those of primitive branchiopods, although the preservation is not sufficient to classify them with certainty. The earliest apparent anostracans are found in the Early Cretaceous epoch. They have trunk limbs very similar to those of recent anostracans. They also have stalked eyes and brood pouches.

Notostracan carapaces have been found in the Carboniferous period (360 to 286 million years ago), and the two extant genera, *Triops* and *Lepidurus,* are known from the Triassic period (245 to 208 million years ago). Some have actually been placed in the living species *Triops cancriformis,* indicating that this species has been in existence for more than 200 million years. The Anomopoda occur as fossils in recent deposits. The families Chydoridae and Bosminidae in particular have been used, in conjunction with pollen and diatoms, to interpret climatic and ecological changes during the histories of individual lakes. Older fossils of anomopods are rare, but egg cases, or ephippia, have been found from the Oligocene epoch (36.6 to 23.7 million years ago) and possibly from the Cretaceous period.

CLASSIFICATION

Distinguishing taxonomic features. Branchiopods are free-living forms, the most primitive members of the phylum Crustacea. They have compound eyes and usually a protective plate, or carapace. There are many body segments and four or more pairs of trunk limbs that are usually lobed, broad, and fringed on the inner side. The mouthparts are small and simple, and the nervous system is primitive. Most species occur in fresh water.

Annotated classification. The groups indicated by a dagger (†) are extinct and known only from fossils.

CLASS BRANCHIOPODA

Distinguishing features include form of trunk limbs and carapace; 8 living and 2 fossil orders.

†Order Lipostraca

Known only from the Devonian; contains only the fossil *Lepidocaris rhyniensis;* 18 segments behind the head, plus telson-bearing caudal rami; no carapace; 13 pairs of trunk limbs in female; antennae large and branched, probably used in swimming; first maxillae small in the female but enlarged in the male as claspers; eggs give rise to nauplius larvae; about 3 mm long.

Order Anostraca

Elongated forms with paired compound eyes on stalks; no carapace; up to 27 body segments behind head, plus a telson with flattened caudal rami; usually 11, but up to 19, pairs of trunk limbs; eggs carried in a brood pouch behind the last pair of trunk limbs; antennae of female simple, but enlarged in the male to form claspers; worldwide; in fresh water, particularly temporary pools, and inland saline waters.

Order Spinicaudata

Large carapace in 2 parts encloses head and trunk; antennae large, branched, and used in swimming; 16 to 32 pairs of trunk limbs, flattened, leaflike, and used in filter feeding; male with first 2 pairs of trunk limbs modified for grasping female during mating; nauplius larvae, except *Cyclestheria;* fossils known from Devonian; recent forms worldwide, except polar regions; in fresh water, usually temporary pools.

Order Laevicaudata

Large bivalved carapace encloses the trunk but not the head; antennae large, branched, and used in swimming; first pair of trunk limbs of male modified for grasping the female during mating, other trunk limbs leaflike and used in filter feeding; nauplius larvae; fossils known from Cretaceous; recent forms worldwide in temporary fresh waters but not in polar regions.

Order Ctenopoda

Short-bodied forms with 6 pairs of trunk limbs, of which 5 bear filters; bivalved carapace encloses trunk but not head; antennae large, used in swimming, and bearing long swimming setae; all filter feeders; no larval stages, young hatch as miniatures of adult; worldwide in fresh water, except Antarctica; one genus, *Penilia,* is marine.

Order Anomopoda

Short-bodied forms with 5 or 6 pairs of trunk limbs; bivalved carapace encloses only the trunk; antennae large, branched, with up to 9 swimming setae; some filter feeders, some scrapers, and 1 genus, *Anchistropus,* parasitic on *Hydra;* no larval stages; resting eggs enclosed in a special case or ephippium; worldwide in fresh water.

Order Onychopoda

Short-bodied forms with carapace reduced to a dorsal brood pouch; 4 pairs of trunk limbs, which only grasp prey; single large median eye with many visual elements; antennae large, branched, with 12–15 swimming setae; freshwater and marine, with radiation into endemic species in the Caspian Sea.

Order Haplopoda

Contains only 1 genus, *Leptodora,* a plankton feeder; carapace reduced to a dorsal brood pouch; large antennae with more than 20 swimming setae; 6 pairs of grasping trunk limbs; head elongated with small, complex eye; transparent except for eye; young develop into miniatures of adult during summer, but overwintering resting eggs give rise to nauplius larvae; found in the fresh waters of the Holarctic region.

Order Notostraca

Large domed carapace covers part of trunk of up to 44 segments; telson with paired, threadlike rami; up to 71 pairs of trunk limbs; elongated first trunk limb functioning as tactile organ; antennae reduced or absent; paired, compound eyes without stalks; eggs, carried in pouches, hatch as nauplius larvae; worldwide except Antarctica; in fresh water, rarely in brackish water, most frequently in temporary pools.

†Order Kazacharthra

Early Jurassic; large carapace covers part of trunk; last 32–40 segments lack limbs; 6 pairs of large trunk limbs project beyond carapace; trunk ends in a large flat telson with a pair of long rami; overall length up to 10 cm.

Critical appraisal. Some authorities classify the Spinicaudata and Laevicaudata as suborders of a single order, the Conchostraca. Many would also group the Ctenopoda, Anomopoda, Onychopoda, and Haplopoda in another single order, the Cladocera. Some would go further and put the Cladocera and Conchostraca together as the Diplostraca. Other alternatives, which have not found general acceptance, are the inclusion of the Cephalocarida within the Branchiopoda, and the use of the groups Sarsostraca and Calmanostraca, the latter including all the orders except the Anostraca and Lipostraca. (J.Gre.)

Cirripedes (barnacles)

GENERAL FEATURES

Diversity and distribution. Barnacles and their allies, the parasitic orders Ascothoracica and Rhizocephala, are sedentary marine crustaceans. Barnacles usually have a calcareous shell made up of a number of articulated plates (Figure 7). The subclass Cirripedia is divided into two superorders, Acrothoracica and Thoracica. Members of the Acrothoracica are known as burrowing barnacles because they burrow into calcareous substrates (*e.g.,* limestone, corals, and mollusk shells). The acrothoracicans are recognized as fossils primarily by their burrows, and, while their record extends back into the Devonian period, they are particularly well represented in the Cretaceous period, when they burrowed into a greater variety of shell-bearing invertebrates than do their modern representatives.

The principal superorder, however, is the Thoracica. It comprises the orders Pedunculata and Sessilia and includes

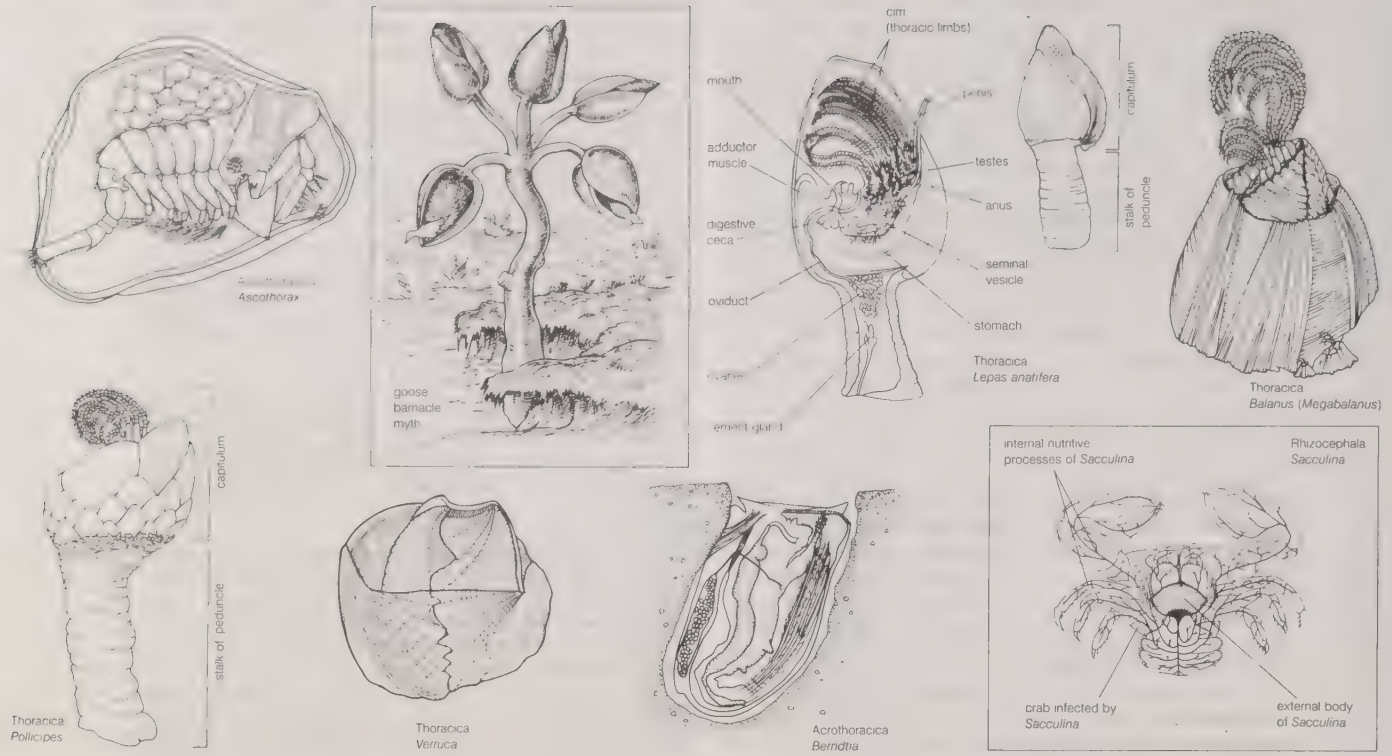

Figure 7: Representative cirripedes.

Modified after (*Ascothorax*) Y K. Okada, *Les Cirripedes Ascothoraciques* (1938), from (goose barnacle myth) *Barnacles in Nature and Myth* (1928) by E. Heron-Allen, Oxford University Press, Inc., reprinted by permission; (*Lepas anatifera*) L.A. Borradaile and F.A. Potts, *Invertebrata*, 4th ed. (1967), Cambridge University Press; (*Verruca*) P.P.C. Hoek, *The Cirripedia of the Siboga-Expedition Siboga-Expeditie XXXI*, (*Berndtia*) H. Utinomi, *Studies on the Cirripedia Acrothoracica* (1960), Seto Marine Biological Laboratory; (others) *Invertebrate Zoology* by Paul A. Meglitsch, copyright © 1967 by Oxford University Press, Inc., reprinted by permission

the goose and acorn barnacles. Thoracicans range from one millimetre (0.04 inch) to more than 10 centimetres (four inches) in diameter and from less than one to more than 500 grams (0.04 to 17.6 ounces).

Symmetrical barnacles

The three suborders of the order Sessilia (sessile barnacles) contain two types of barnacles: symmetrical and asymmetrical. The two symmetrical sessile barnacles are the extinct suborder Brachylepadomorpha (*Brachylepas*) and the suborder Balanomorpha, or acorn barnacles (*e.g., Balanus, Semibalanus,* and *Chthamalus*). An acorn barnacle is a conical, sessile animal whose soft body is contained within a cavity protected by an outer wall. This wall comprises an even number of calcareous plates cemented to the substratum. An opening at the top can be closed by two pairs of plates (an operculum) through which feathery, jointed legs (cirri) can be extended into the water to capture small drifting plants and animals (plankton).

The balanomorphs are now the dominant shallow-water barnacles. Species are found in almost all habitats, from equatorial to polar regions, from estuarine waters and the highest intertidal zones to depths of 2,000 metres (6,560 feet) or more. Several groups of commensal balanomorphs have formed symbiotic associations with a variety of hosts, but only a few are known to have become fully parasitic. The most primitive living genera, such as *Chionelasmus* and *Catophragmus,* appeared in the late Mesozoic era (245 to 66.4 million years ago) and early Tertiary period (66.4 to 1.6 million years ago). Modern representatives are distributed throughout the world in refugial situations, such as abyssal hydrothermal springs.

The third suborder of sessile barnacles, the Verrucomorpha, or wart barnacles, differs from the first two suborders in having the plates of the wall and operculum asymmetrically arranged. With the exception of a primitive genus, *Neoverruca,* found to be associated with abyssal hydrothermal springs at 3,600 metres in the western Pacific, the simple, asymmetrical shell wall and operculum of verrucomorphs are remarkably similar. While the verrucomorphs apparently radiated in relatively shallow-water seas of the Cretaceous period, their modern representatives primarily inhabit the deep sea, where they range to depths of more than 4,000 metres.

Pedunculate barnacles

Members of the second thoracican order, Pedunculata, are similar to the sessile barnacles in having the principal part of the body contained within a protective covering, or wall. They differ from acorn barnacles in that the plates do not form a separate wall and operculum and in having the wall and the cirri it contains elevated above the substratum by a peduncle. The peduncle contains the ovaries and some musculature; it may or may not be armoured by calcareous plates, as in *Pollicipes* and *Lepas,* respectively. Goose barnacles are probably the most commonly observed pedunculate cirripedes.

Pedunculate barnacles occupy a wide variety of substrates. At least half the living species are symbiotic to some degree, and a few have become fully parasitic. In general, however, pedunculate barnacles have not formed as intricate symbiotic relationships as have a variety of balanomorphs. The pedunculate barnacles are fairly well represented in the fossil record, especially in the Mesozoic, but the earliest records date back to the Cambrian period (570 to 505 million years ago) and the Silurian period (438 to 408 million years ago).

Parasitic allies of barnacles

There are two parasitic groups: the order Rhizocephala, found primarily on decapod crustaceans, and the order Ascothoracica, found on echinoderms and cnidarian corals. While they are not included in the Cirripedia in the classification used in this article, they have been so included and therefore will be considered here.

Importance to humans. There are about a dozen important species of sessile and pedunculate barnacles that foul ships and submerged portions of marine installations, such as pier pilings, oil platforms, floats, buoys, and mooring cables. This causes drag and increased weight and may also increase corrosion of metals, even stainless steel. Antifouling paints contain toxins (usually heavy metals) and are designed to slough off with age. Low- and high-frequency sound waves may effectively inhibit settling. Ships and shore installations that circulate seawater for various purposes may have problems with lines clogged by fouling organisms. Various methods of prevention or removal, such as back-flushing with heated water or flushing with chemicals or fresh water, have been used with success.

Barnacles are used as food in some countries. In Por-

tugal and Spain a local intertidal pedunculate barnacle, *Pollicipes pollicipes,* is served in gourmet restaurants and occasionally becomes locally depleted. Two related species in the eastern Pacific, *P. polymerus* and *P. elegans,* from the northeastern and tropical eastern Pacific, respectively, are often imported as substitutes. Indians of the American Pacific Northwest consume the large sessile barnacle *Balanus nubilus,* and the inhabitants of Chile eat yet another large balanid species. In Japan barnacles are used as fertilizer.

The cement by which barnacles attach themselves to the substratum sets under water and even sticks to plastics with low surface tensions. It has been investigated because of its unusual properties and possible use in dental applications.

Goose barnacle myth

In the western British Isles during the Middle Ages a prevalent myth involving barnacles purported to explain the annual appearance of certain geese in the fall. Because these geese were arriving from their summer breeding grounds north of the Arctic Circle, they were not observed to breed locally. At the same time, fall gales often blew ashore driftwood fouled by the pedunculate barnacle *Lepas.* The barnacle myth correlated these occurrences; namely, according to the myth, the barnacles, which appeared to grow out of wood steeped in seawater, were actually developing geese, and, indeed, goose feathers (the barnacles' cirri) could be seen within. Further, since these geese were believed to have come from shellfish rather than flesh, they could be eaten on fasting days. The Swedish botanist Carolus Linnaeus was aware of the myth, for he named the genus *Lepas* ("Shellfish") and the local species *L. anatifera* and *L. anserifera* ("duck-bearing" and "goose-bearing," respectively), and these pedunculate barnacles continue to be called goose barnacles.

NATURAL HISTORY

Reproduction and life cycles. Barnacles generally have both male and female reproductive systems in the same individual (hermaphroditism), either or both of which can be active at one time. Although some species are known to self-fertilize if no partners are present, most shallow-water species cross-fertilize. In species in which populations are sparsely distributed, a hermaphrodite may be accompanied by one or more small "complemental" males, or the larger individual may develop into a female whereby a smaller individual attaching to it becomes a "dwarf" male. When the male occupies a fairly exposed position on its partner, it resembles the juvenile and is capable of feeding. When, through coevolution, males have come to be protected by the partner in one way or another, the dwarf male is variously reduced, some to the extent of being little more than a sac containing the testes.

Dwarf males

Adjacent individuals in normally hermaphroditic populations do not simultaneously cross-fertilize; rather, they alternate male and female roles over time. The individual acting as a female lays eggs inside the mantle cavity shortly after molting (Figure 8). Secretions associated with egg laying include a pheromone to which adjacent individuals respond by extending the prosbosciform penis toward the source. Barnacles acting as males are able to inject spermatozoa into the mantle cavity of an individual as far as seven shell diameters away. Hundreds of eggs contained in this mantle cavity are fertilized at one time; usually several batches are laid each year by adults that may live as long as 30 years. The eggs undergo spiral cleavage, and the developing embryos are retained until the first larval stage, called the nauplius. In some species, however, the naupliar stages are passed in the egg, and a cyprid larva is released into the plankton.

The nauplius larva of crustaceans (Figure 8) has three pairs of cephalic limbs, all of which aid in swimming while the second two are further involved in feeding. Cirripede and rhizocephalan nauplii differ from those of other crustaceans, including the Ascothoracica, in having conspicuous horns on either side near the front on the head. These horns have perforated tips and are provided with large secretory cells, but their function has yet to be determined.

Larval forms

Shortly after they hatch from the egg membranes and are expelled from the mantle cavity, the weak-swimming nauplii molt and begin to feed; the diet, primarily phytoplankton, depends upon the species. The nauplii continue to grow and molt for about two weeks, after which the sixth stage is reached. At this point a profound metamorphosis takes place, resulting in a nonfeeding, relatively strong-swimming cyprid larva (Figure 8). The cyprid must find a suitable surface upon which to settle in a relatively short time, or it will die. Substrate selection is based on light and chemical and tactile stimuli; it is likely that pheromones play a role when sexual selection is involved.

The cyprid swims with six pairs of thoracic limbs (the cirri of the adult). Gregarious forms are attracted by tactile stimuli to established members or to their remains, while commensal and parasitic species, many of which are host-specific, also use chemical stimuli to detect a suitable host. When ready to attach, the cyprid explores using its first antennae, the ends of which stick to the substratum by a temporary cement. When an appropriate place is found, similar glands secrete a permanent cement. The cyprid then undergoes metamorphosis into a juvenile barnacle.

Metamorphosis of a cyprid is complicated, some parts being temporarily or permanently lost, others modified and rotated, and still others appearing anew. The first juveniles of pedunculate barnacles are pedunculate, but pedunculate stages have been virtually eliminated from the development of modern sessile barnacles.

Meta-morphosis

The rhizocephalans have an unusual life cycle. A cyprid destined to become a female seeks out a host, such as a crab, and attaches where the cuticle is thin, usually on a gill or at the base of a seta. The cyprid metamorphoses, and all body parts, except certain cells and organ rudiments of the head, are discarded. When this process is completed, a hollow, ventral stylet is, depending upon the species, forced either directly into the host or into the host after passing through one of the cyprid's first antennae. Once in the host's body, the cells and organ rudiments migrate into a central position beneath the gut, where they then send out rootlike absorption processes to all parts of the crab's body. The presence of the parasite not only castrates the host but it also feminizes a male host during subsequent molts both in morphology and behaviour.

Once the parasite has established itself internally, a hollow, mushroomlike reproductive body develops and perforates the ventral cuticle of the host between the thorax and the abdomen. There it enlarges to fill the space where the crab normally broods its eggs, and there the crab cares for the parasite as if it were its own eggs.

If a rhizocephalon cyprid destined to be a male finds the freshly erupted female, it attaches near the brood chamber and undergoes a similar metamorphosis into a minute cell mass surrounded by a thin cuticle. The cell mass migrates into the female's brood chamber, where it finds a special

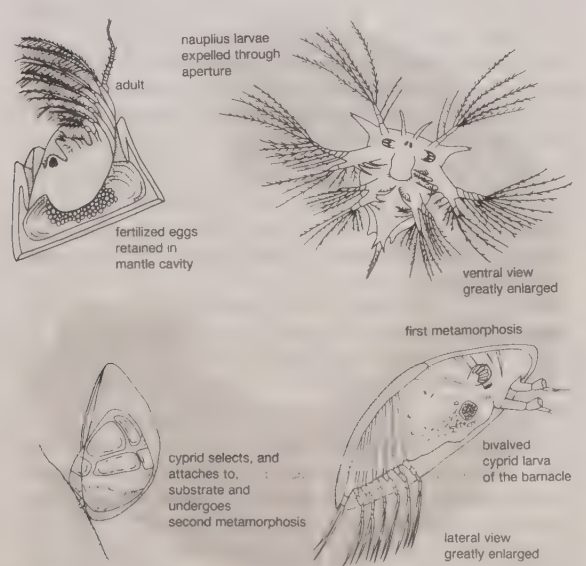

Figure 8: Life cycle of a typical acorn barnacle.

pocket, or male-cell receptacle. It discards the cuticle as it enters the receptacle and differentiates into spermatozoa. Fertilization occurs when the eggs are laid, and the developing larvae are retained in the cavity until hatching. When the rhizocephalan is ready to release the larvae, the crab starts a ventilating motion with its abdomen, just as it would if it were releasing its own larvae, dispersing the parasite's larvae into the prevailing currents.

Larval dispersal. Larval dispersal depends upon the time spent and the behaviour of the various stages, as well as on favourable currents while in the plankton, prior to cyprid settlement. Larvae do not remain in the plankton for more than a few weeks, and larval dispersal is generally limited to less than 1,000 kilometres (620 miles). Species, however, are found on oceanic islands isolated by much greater distances, in part because some benthic barnacles occasionally attach to larger animals such as fish and whales as well as to floating objects such as wood, kelp, and pumice.

Associations

Still other barnacle species develop a symbiotic relationship with an organism, such as a whale, turtle, sea snake, or jellyfish (ectocommensal), and their distributions tend to approximate those of their hosts. In some instances, however, the distribution of the barnacle is only a small portion of that enjoyed by its host, indicating that other factors limit its range.

In the open ocean the larvae of the pedunculate barnacle *Lepas* seek out objects generally large enough to support the weight of the numerous adults (*e.g.,* driftwood). There is one species, however, that selects small objects (*e.g.,* feathers, bits of tar). After metamorphosis the cement glands of this species secrete a multichambered gas-filled float of its own. Floating objects attract other planktonic organisms, such as copepods and small fish, on which the barnacles feed.

FORM AND FUNCTION

External features. It has been said that a barnacle is a shrimplike crustacean that attaches by the top of its head and then kicks food into its mouth with its feet. This likely tongue-in-cheek definition actually distinguishes barnacles from their allies and gives a fair idea of how the animal operates. Furthermore, a sedentary way of life requires protection from many biological and physical situations that can readily be avoided by their motile, free-living counterparts.

A thin, chitinous cuticle covers the appendage-bearing portion of the body, including the cirri, mouthparts, and lining of the mantle cavity. This portion of the exoskeleton is molted periodically, the process being controlled by hormones.

Internal features. *Tissues and musculature.* The tissues and organs of the barnacle are bathed by blood, which sometimes contains dissolved hemoglobin. In contrast to most crustaceans, however, the blood circulates in a generally closed system. Blood pressure extends and distends the stalk in pedunculate barnacles; the relatively long cirri, which are curled while at rest; the trunk of the body that supports the cirri; and the prosbosciform penis. The principle pair of plates covering over the mantle opening is provided with a transverse adductor muscle and discrete retractor muscles.

The nervous system. The nervous system, ladderlike in some primitive pedunculate barnacles, is condensed in scalpellomorphans and sessile barnacles into a single mass. The second antennae are present in nauplii but lost in cyprids. The first antennae are used by the cyprid in settling, but become buried in the permanent cement following attachment. The lateral, compound eyes of the cyprid are shed with metamorphosis. The nauplius median eye is generally retained in the adult as a photoreceptor. In sessile barnacles the bilateral parts of the median eye separate and migrate laterally to thin places under the anterior pair of opercular plates, where they function better in the shadow reflex. This reflex results in the rapid withdrawal of the cirri, which are otherwise vulnerable to predation, especially by fish.

The digestive system. Food gathered by the posterior cirri is collected and passed to the mouthparts by anterior cirri modified to act as maxillipeds. As it is pushed under an upper lip and into the mouth, the food is masticated by the two pairs of spiny maxillae and then by toothed mandibles. Salivary glands generally empty on the second maxillae and provide secretions that stick the food particles together and transport them to the mouth.

As in most crustaceans, a short foregut leads to a spacious midgut, or stomach, usually provided with a pair of digestive pouches, or ceca. The midgut is followed by a relatively long hindgut that passes the length of the trunk to the anus located between the last pair of cirri. The acrothoracicans have a gastric mill, derived from the chitinous lining of the foregut and renewed after being discarded during molting.

The excretory system. Maxillary glands are well-developed in adults, where they open just behind the base of the second pair of maxillae. Barnacles are also able to sequester heavy metals and brominated compounds as nodules in the wall of the midgut.

Open circulatory system

The circulatory system. As noted above, the circulatory system is a modification of the relatively simple, open system seen in crustaceans. In barnacles, pumping has largely been assumed by the somatic musculature, and in mature and advanced forms a nearly closed system of walled vessels has developed. Gas exchange can take place across any of the thin cuticular surfaces of the body, and many small barnacles lack discrete respiratory organs.

The cirri form excellent respiratory structures when the animals are feeding, and water can be circulated in and out of the mantle cavity by pumping movements of the body when the cirri are withdrawn and the aperture to the exterior is not completely closed. Some pedunculate barnacles have straplike organs, called filamentary appendages, extending from the body wall. On the other hand, most sessile barnacles have a pair of broad, often wrinkled extensions of the mantle wall, called branchiae. These and filamentary appendages are considered respiratory organs.

Ovaries and testes

The reproductive system. Ovaries are located in the stalk of pedunculate barnacles and its homologue or in the basal lining of the mantle cavity in sessile barnacles. Paired oviducts pass posteriorly to the bases of the first cirri (the most anterior position for genital openings in any crustacean), where each is joined by an oviductal gland before emptying into the mantle cavity. The oviductal gland secretes a tacky elastic substance that mixes with eggs as they are laid and holds them in one or two discrete masses called ovigerous lamellae.

Testes are situated in the trunk. Paired sperm ducts pass posteriorly below and to the sides of the gut before each expands into a seminal vesicle. An ejaculatory duct enters the base of the prosbosciform penis, situated between the last pair of legs, and runs its length. The penis may be clothed with fine setae, randomly distributed or arranged in discrete rows, or modified into simple or complex spines and hooks.

The nondistensible penis in ascothoracicans is a less-extensive modification of the seventh pair of trunk limbs seen in more primitive crustaceans. It is used to inject spermatozoa into special chitinous seminal receptacles in the bases of the trunk limbs of the female, where they are stored until the eggs are laid. The prosbosciform penis of acrothoracicans and ordinary barnacles injects the spermatozoa into the mantle cavity of the female, or a hermaphrodite acting as a female, at the time the eggs are being laid.

Hormones. Although sites of neurosecretory and glandular hormone production have not been identified in barnacles, molting and metamorphosis are controlled by hormones. Two insect molting hormones have been identified in the barnacle.

EVOLUTION AND PALEONTOLOGY

The Cirripedia belong to the class Maxillopoda, an ancient radiation of relatively small, primarily marine crustaceans presently known by 11 subclasses, five of which (Branchiura, Facetotecta, Tantulocarida, Ascothoracica, and Rhizocephala) are wholly parasitic. Of the six nonparasitic subclasses the Ostenocarida and Skaracarida are

extinct (Cambrian), and the Mystacocarida are generally restricted to a narrow band of the marine interstitial environment. On the other hand, of the primarily nonparasitic groups, the Ostracoda and Cirripedia, ranging from the Cambrian period, and the Copepoda are diverse and occupy a wide variety of aquatic habitats. Of the nonparasitic groups, only the mystacocarids and cirripedes are exclusively marine.

Because of marked similarities in their nauplius and cyprid larval forms, it has generally been considered that the Cirripedia gave rise to the highly modified parasitic Rhizocephala. This view has been appealing because two parasitic pedunculate barnacles draw nutrients from their hosts by a root system, which, if not homologous with that of the Rhizocephala, at least indicates how the rhizocephalans could have evolved from a parasitic barnacle. The mode of host penetration by a stylet near the area of the cyprid mouth and the composition of the injected material, however, indicate that the Rhizocephala evolved from a biting rather than a filter-feeding ancestor and therefore more likely represent a sister group than a derivative of the Cirripedia.

At times the parasitic Ascothoracica also have been included in the Cirripedia because of a similar body plan. They have, however, a nonprobosciform median penis and seminal receptacles, as well as trunk limbs used solely for swimming, that show no indication of ever having been involved in filter feeding. Furthermore, their nauplius larvae lack frontolateral horns, and their cypridlike larvae (often more than one stage) not only are capable of feeding with biting mouthparts but also possess distinctive prehensile first antennae that lack cement glands. Thus, the Ascothoracica are no longer included in the Cirripedia. They share, however, a common nonparasitic ancestor with the parasitic Rhizocephala and Cirripedia, on one hand, and the Facetotecta, on the other. A category that had fallen into disuse, the Thecostraca, is therefore now being used to accommodate these subclasses.

A comparable nonparasitic ancestor was apparently shared by the Tantulocarida since a median nonprobosciform penis occurs on the same segment as in ascothoracids. While the posterior portion of the trunk in the Branchiura is too reduced to be instructive along these lines, the Ostracoda and the extinct Ostenocarida have a pair of penes and a pair of unmodified legs in the same position, respectively, and therefore are apparently nearer the stem of this Cambrian radiation. The Copepoda, Mystacocarida, and extinct Skaracarida, while lacking male genitalia and other features, such as a carapace and lateral eye, apparently also stem from near the base of this radiation in the Cambrian period.

Few Paleozoic barnacles are known. The acrothoracicans, or rather characteristic burrows made by them, appear in the Devonian period, but what they were like before they acquired the ability to burrow is unknown. The lightly armoured pedunculate barnacles *Priscansermarinus* and *Cyprilepas* appear earlier, in the Cambrian and Silurian periods, respectively, and what could pass for contemporary pedunculate barnacles, *Praelepas* and *Illilepas,* appear in the Carboniferous period. The first resembles heteralepadomorphs (genera without a trace of calcareous or primordial chitinous plates), and, other than being uncalcified, the last two resemble lepadomorphans *Lepas* and *Ibla,* respectively.

Heavy calcareous (calcitic) armament first appears in the Scalpellomorpha in the early Mesozoic era (245 to 66.4 million years ago), and by the close of the early Mesozoic the three sessile groups—Brachylepadomorpha, Verrucomorpha, and Balanomorpha—appear in order. The most primitive sessile group, the Brachylepadomorpha, died out by the Miocene epoch (23.7 to 5.3 million years ago), and the asymmetrical sessile Verrucomorpha became pretty much restricted to the deep sea by that time. The Balanomorpha radiated up through the Tertiary, and it is largely on the basis of their remains that Charles Darwin noted that the present epoch could go down in the fossil record as the age of barnacles. It is evident, however, that there was a greater diversity of shallow-water barnacles in the Miocene than there is today.

CLASSIFICATION

Annotated classification.

SUBCLASS (ORDER) CIRRIPEDIA

Maxillopodans; distinguished from nonparasitic crustaceans in being sedentary as adults; feeding by cirri; attached in burrows in limestone, corals, and shells or on a variety of substrata; usually provided with permanent, commonly calcareous armament; female genital apertures open on first trunk segment; male genital aperture opens on a probosciform median penis on the sixth trunk segment; parasitic isopods (malacostracans); differentiation of the carapace, skeletal armature, and appendages taxonomically significant; approximately 1,000 species known.

Superorder Acrothoracica (burrowing barnacles)

Devonian to present; globular in shape; generally without conspicuous calcareous exoskeleton; posterior cirri concentrated at end of trunk; widely distributed in coralline seas, most primitive members in deep sea; approximately 1 mm in length.

Superorder Thoracica (barnacles)

Cambrian to present; conspicuous calcareous exoskeleton; posterior cirri evenly distributed along trunk; inhabit virtually all marine environments, several primitive members in the deep sea; 1 mm to 2 cm in length, some larger.

Order Pedunculata (stalked or pedunculate barnacles)

Cambrian to present; body generally divided into capitulum and peduncle; capitular armament not differentiated into wall and operculum; includes 6 suborders, 2 extinct (Cyprilepadomorpha and Praelepadomorpha) and 4 extant (Heteralepadomorpha, Iblomorpha, Lepadomorpha, and Scalpellomorpha), the 3 best-known characterized below.

Suborder Iblomorpha. Carboniferous? to present; spindle-shaped capitulum/peduncle clothed with stiff chitinous bristles, supporting 2 pairs of sometimes slightly calcified plates; carapace adductor in primitive position, located posterior rather than anterior to esophagus; marine; 2 mm to 2 cm in length.

Suborder Lepadomorpha (goose barnacles and allies). Triassic?, Middle Eocene to present; capitulum typically with 5 calcareous plates; peduncle without calcareous armament; 3 mm to 75 cm in length.

Suborder Scalpellomorpha (leaf barnacles and allies). Triassic to present; capitulum supporting 6 or more calcareous plates; peduncle usually armoured with calcareous scales or spicules; 2 mm to 10 cm in length.

Order Sessilia (operculate or sessile barnacles)

Late Jurassic?, Cretaceous to present; capitulum relatively rigid; cemented directly to the substratum; supporting an operculum of 2 or 3 movable plates, or 2 to 3 pairs of movable plates; transient peduncle, disappearing early in ontogeny, forms the floor of capitulum in adults.

Suborder Brachylepadomorpha. Late Jurassic?, Triassic to Miocene; principal capitular plates and undedicated lateral plates; usually supporting 3 pairs of opercular plates; elevated above substratum by several basal whorls of imbricating plates; 1 to 2 cm in height.

Suborder Verrucomorpha (wart or asymmetrical sessile barnacles). Cretaceous to present; 2 or 3 plates on the right or left side form movable operculum; of those of the opposite side, 1 lost and 2 immovably incorporated into wall; primitive species with basal whorls of imbricating plates elevating the wall above the substratum; all basal imbricating plates lost in higher forms, the highest being reduced to a 2-plated operculum and a 4-plated wall cemented to the substratum; 2 mm to 2 cm in height.

Suborder Balanomorpha (acorn barnacles). Late Cretaceous to present; operculum of 2 pairs of plates supported by a rigid wall, including up to 3 pairs of dedicated lateral plates; principal wall cemented directly to the substratum, even when surrounded by basal whorls of imbricating plates; 2 mm to 10 cm in height and diameter, may reach 23 cm in height.

Critical appraisal. Some authorities, such as the author of the overview section above, rank the cirripedes as an order. The Rhizocephala, although closely related by larval similarities (including nauplii with frontolateral horns and a cyprid with prehensile first antennae provided with cement glands), are not included in the Cirripedia by some researchers. Also no longer included in the Cirripedia are the Ascothoracica, which have nauplii that lack horns, cypridlike larvae whose first antennae, while prehensile, lack cement glands, and males that have a nonprobosciform median penis.

Evidence from relatively recently discovered fossil and living taxa indicates that the Maxillopoda quite possibly include two natural lineages stemming from a common

ancestor in the Cambrian. If the definition of the Thecostraca, which presently includes the Facetotecta, Ascothoracica, Rhizocephala, and Cirripedia, were expanded to include all the maxillopodan subclasses also having a carapace and lateral eyes (Tantulocarida, Ostracoda, Branchiura, and Ostenocarida), and if the Copepodoida (originally equivalent to the Maxillopoda) were restricted to include the maxillopodan subclasses without a carapace and lateral eyes (Copepoda, Mystacocarida, and Skaracarida), it would likely better reflect the relationships within the class. (W.A.N.)

Malacostracans (lobsters, shrimps, crabs, scuds, and pill bugs)

Malacostracans are the most numerous and most successful of the four major classes of Crustacea. Their members constitute more than two-thirds of all living crustacean species. They exhibit the greatest range of size (less than one millimetre, or 0.04 inch, to a limb spread of more than three metres, or 10 feet) and the greatest diversity of body form. Malacostracans are abundant in all permanent waters of the world: in the seas from the tropics to the poles and from the tidal zone to the abyss; in surface and subterranean fresh waters of all continents except Antarctica (where they once existed); and terrestrially on all continental landmasses and all tropical and temperate islands.

Successful radiation

The success of malacostracans can be attributed primarily to their increased body size and to the evolution of more functional body regions and more sophisticated food-gathering appendages than possessed either by their Paleozoic ancestors (570 to 245 million years ago) or by the next largest living crustacean class, the Maxillopoda. This evolutionary thrust has been marked by the development of ambulatory legs and specializations for benthic life and by the brooding of eggs and suppression of free-living larval development. Especially significant has been a shift of food-gathering limbs from head to thorax and of swimming appendages and respiratory organs from head to thorax and finally to the abdomen. This rearward shift freed the antennae for the development of specialized organelles sensitive to odours, sounds, vibrations, and physical contact and added more appendages (maxillipeds) to the mouthpart field. Such changes have enabled malacostracans to utilize efficiently the new food resources that have accompanied the evolution and proliferation of vascular plants from the late Paleozoic to the present.

GENERAL FEATURES

Size range and diversity of structure. Malacostracans are typically large in size. Thus, some decapod crabs have leg spans of more than three metres, and others weigh more than 10 kilograms (22 pounds). Some free-living members of the orders Amphipoda, Isopoda, and Stomatopoda are lobster-sized (25–30 centimetres [0.8 to one inch]); most, however, are medium (one to three centimetres) in size. Paleozoic and primitive extant taxa seldom exceed 10 centimetres in body length, and the adult stages of some parasitic and subterranean groups are very small (less than one millimetre).

From J. Klövekorn, "Das Organsystem der Blutbewegung bei Gammarus," *Zeitschrift für Wissenschaftliche Zoologie*, Bd. 146 (1935)

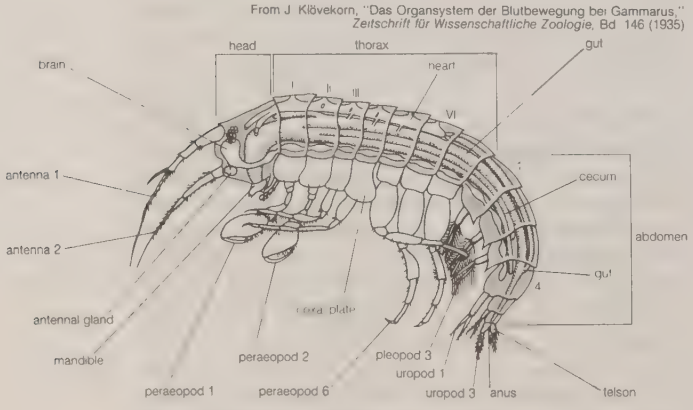

Figure 9: Anatomy of a gammaridean amphipod.

Malacostracans have a fixed body plan of head, thorax, and abdomen (Figure 9). In the adult the head consists of five segments, the thorax of eight, and the abdomen typically of six (or rarely seven) unfused segments. The head supports paired compound eyes, two pairs of antennae, and three pairs of short, chewing mouthparts, each consisting of two branches. The eyes are usually pigmented and borne on movable stalks, but they are sessile on the sides of the head in isopods, amphipods, and the superorder Hemicaridea. The first antennae (antennules) usually have two branches (three in the subclass Hoplocarida). The outer branch of the second antennae (antennal squame), which is usually flat and bladelike for elevation and swimming balance, has two segments in stomatopods and some mysids and one segment in syncarids and eucarids; it may be small or lost entirely in amphipods, isopods, and other bottom-dwelling or subterranean taxa. The first and second maxillae are short, with variable numbers of inner biting plates (endites) and often with outer lobes (epipodites), but the palps are short or lacking.

Carapace

From the hindmost (maxillary) segment projects a head shield, or carapace, which in primitive forms is large and covers the thorax, leg bases, and gill chamber. It may be fused to the dorsum of the thorax, as in the superorder Eucarida, but it is variously reduced and fused only to the anterior thoracic segments in the superorder Hemicaridea and the order Mysidacea or lost altogether in the orders Isopoda and Amphipoda and the superorder Syncarida.

The thoracic legs are typically biramous and eight in number. In free-swimming taxa the legs are more or less alike, and both branches are slender. In bottom-dwelling taxa the inner branch has become a stiff walking limb, and the slender multisegmented outer branch is variously reduced (in hemicarideans) or lost altogether (in amphipods and isopods). In advanced, especially bottom-dwelling, malacostracans, one or more legs are pincerlike.

Limbs

The abdomen bears on each but the last segment a pair of ventral, or ventrolateral, biramous limbs called paraeopods, or pleopods, which are primarily used in swimming. In the males of all eucaridans, hoplocarids, isopods, some hemicarids and syncarids, and rarely some amphipods, the anterior one or two pairs may be specially modified for sperm transfer. In males of most mysidaceans, the fourth and fifth pleopods (and the first and second uropods of some amphipods) may be modified as claspers for holding the female during copulation. The last abdominal segment (of all but the leptostracans) bears a pair of biramous uropods and a median plate, or telson. The uropods are usually setose and paddle-shaped in swimming taxa and form a broad tail fan with the telson for rapid propulsion. In benthic and subterranean taxa the uropods are often slender, elongate, and tactile in function. The telson is bilobed in juvenile syncarids, larval eucaridans, some mysids, and most amphipods but platelike in all other malacostracans.

Distribution and abundance. The class Malacostraca contains more than 22,000 living species and represents about two-thirds of all known crustaceans. It is the single largest group not only of marine arthropods but also of all fully aquatic arthropod taxa, including the insects and arachnids. Within the Malacostraca, Decapoda is the largest order, with about 9,000 described species, followed by the orders Amphipoda (6,200 species) and Isopoda (4,600 species). The other major orders have fewer than 1,000 species each.

Most malacostracans are marine. Among the decapods the ancient palinurans, their modern brachyuran (10-legged crab) derivatives, and the dendrobrachiate and stenopodid shrimps dominate in tropical and temperate marine shallows. The decapod caridean shrimps, astacidean lobsters and crayfish, and anomalans (hermits and eight-legged crabs), however, are dominant in cold-water and polar regions, in the deep sea, and in continental fresh waters. The amphipods and isopods are also abundant along cold-water marine shores and in the abyss and have widely penetrated fresh waters. They are also widespread in underground waters and terrestrial environments. Stomatopods are largely confined to tropical marine shallows; tanaids and cumaceans are found mainly in the colder deeps;

and mysids, though mainly marine, are also abundant in relicts of northern glacial lakes.

Importance to ecology and to humans. Malacostracans, being large crustaceans, are often predators and scavengers and thus are found at or near the top of the aquatic food pyramid. They are important ecologically in ridding the sea bottom and seashores of decaying animal and plant matter and in serving as middle-level converters of organic food energy to animal protein in a form suitable for fish, sea birds, marine mammals, and ultimately humans. The decapods and the order Euphausiacea (krill) are the only malacostracan groups of major economic value to humans.

NATURAL HISTORY

Reproduction and life cycles. The life cycle of malacostracans typically involves an egg stage; a series of free-swimming, plankton-feeding larval stages; a series of immature (subadult) growth stages; and finally a sexually mature (reproductive) adult stage. Hermaphroditic adults are present in a few isopods. In the primitive swarming type of reproduction the male seeks out the female in the open water, usually in synchrony with lunar periodicity, cycles of temperature, or food availability. Mating (copulation) is very brief, often completed in a few seconds and usually following the reproductive molt of the female, when her exoskeleton is still soft. The eggs are fertilized as they are extruded from the oviductal opening on the sternum of the sixth thoracic segment. The anterior pleopods of the male are typically not modified for the transfer of sperm from the genital opening(s) on the eighth thoracic segment (*e.g.,* in amphipods and primitive decapods). Such males usually do not feed, do not reproduce again, and do not live long after mating. Fertilized eggs may be shed freely in the sea, where they hatch, usually into nauplius larvae. In marine groups that brood the eggs by attaching them to the pleopods, the eggs hatch as late-stage larvae, which are often carnivorous (*e.g.,* zoeae and phyllosoma larvae of decapods, antizoeae and pseudozoeae of stomatopods). These larvae eventually drop to the bottom and pass through one or more stages prior to attaining the immature stage. Where eggs develop within a thoracic brood pouch, the larval stages are suppressed. The eggs hatch as well-developed embryos (in the order Leptostraca) or as immature forms of the adult (*e.g.,* Isopoda, juveniles of the orders Mysidacea and Amphipoda), but parental brooding may be continued for a further few molts. In the deep sea and in fresh waters, whether eggs are laid freely (superorder Syncarida) or brooded on pleopods (decapods) or in a thoracic pouch (isopods and amphipods), the eggs hatch as juveniles or immature adult forms.

Mating

In the more-advanced, especially bottom-dwelling, malacostracans or in those with specialized habits, mating usually takes place on or in the bottom. Males may attend, guard, or carry the female for some time (preamplexus) prior to copulation (amplexus), and mating may be prolonged for several hours; the male usually continues to feed, molt, and mate further (in isopods, creeping decapods, and benthic amphipods). Where the female exoskeleton variously hardens prior to mating, the oviductal opening is often complex, and sperm transfer is assisted by correspondingly modified first and second pleopods of the male ("internal" fertilization of stomatopods, isopods, and the superorder Eucarida). Newly hatched late larvae or juveniles may be initially guarded or carried by the female (in stomatopods and some amphipods and isopods).

Locomotion. Malacostracans are primarily swimmers and secondarily walkers, clingers, and burrowers. Swimming is accomplished primitively by coordinated, synchronous beating of the setae on the outer branches of biramous head appendages in early larval stages and thoracic appendages in later larval stages and the adult stages of the order Leptostraca, the order Mysidacea, and the superorders Syncarida and Eucarida. The swimming action characteristic of adult malacostracans is provided by abdominal pleopods. Typically, each of the first five abdominal segments bears, on the ventral (lower) surface, a pair of pedunculate, biramous pleopods. In order to beat in unison, each pair is usually hooked together by spines on the inner margin of the peduncle (retinacula) or the inner ramus ("clothespin spines"). The amphipods are unique in having only three pairs of pleopods, the last two pairs being modified as stiff, thrusting uropods. In primitive forms the pleopod rami are slender and segmented (annulate), as in amphipods and procaridid decapods, all of which are primarily swimmers as adults; however, in all the other malacostracan groups, most of which are crawlers and burrowers, the rami are broad, flaplike, and unsegmented. The pleopods are typically reduced, or even lost, in many burrowers. The swimming crabs use paddle-like fifth thoracic legs for propulsion. Abrupt swimming propulsion is provided by the tail fan. In amphipods the tail fan (consisting of three pairs of uropods and telson) provides a sudden forward thrust. In eucaridans (especially decapods) the tail fan (paired uropods and telson) provides a characteristic "tail-flip" or sudden backward escape reaction.

Swimming

In most benthic malacostracans the hind five to seven pairs of thoracic legs have become essentially uniramous—the inner branch is thickened and stiffened and adapted for walking or crawling. In amphipods the first four pairs are pointed forward and the last three backward, an adaptation for perching, clinging, climbing in "inchworm" fashion, or jumping.

In burrowing malacostracans, especially decapods and stomatopods, the distal segments of some legs attain a semichelate, subchelate, or true chelate (pincerlike) form that facilitates both digging and removal of the soft substratum. In many amphipod burrowers the claws are often reduced, but the adjacent segments are much broadened, strongly spined, and powerfully muscled. Rapid leg movements, often aided by the fanning action of setose antennae and the hydraulic tunneling motion of powerful pleopods, enable these torpedo-shaped crustaceans to swim through loose sandy substrata, feeding as they go.

Food and feeding. Malacostracans consume virtually every available kind of organic matter, plant or animal, living or dead. The small- to medium-sized groups primarily consume detritus and plankton, and some are parasites of other aquatic organisms. The larger-sized groups are mainly carnivores and scavengers, preying on a wide range of small invertebrates and fishes or devouring the carcasses of whales, seals, fishes, and large invertebrates. Burrowing and small groundwater malacostracans are filter feeders, consuming microorganisms and bacteria from the sediments. Terrestrial isopods and amphipods consume forest leaf litter and algae at the tide lines.

Malacostracans capture or obtain their food primarily by using their thoracic legs. In early free-swimming larvae and the adults of some filter-feeding or deposit-feeding amphipods, isopods, and hemicarideans and in large carnivorous palinuran decapods, food may be gathered (occasionally killed) by means of the antennae and other head appendages. In carnivorous, or raptorial, species one or more of the thoracic legs are enlarged, and the tips are pincerlike, allowing the animal to capture, kill, and initially shred its prey (Figure 10). In lobsters and crayfish the first walking leg (fourth thoracic) is fully cheliform, and either the left or right claw is massive, with pavementlike teeth, for crushing hard-shelled prey such as snails and clams. In "spearer"-type stomatopods the raptorial claw is toothed and spiny for stabbing soft-bodied prey. "Smashers" have a swollen, hammerlike claw for crushing hard-bodied prey.

Capturing food

Malacostracans (except for leptostracans) typically have one to three pairs of thoracic limbs modified as accessory mouthparts. These maxillipeds (or "jaw legs") pass food to the masticatory, or chewing, mouthparts of the head proper. The thoracic segment of the first pair of maxillipeds is usually fused to the head, forming a cephalon (Figure 9). In stomatopods the first five pairs are called maxillipeds, but only the first pair is functionally so and its body segment is not fused to the head. In amphipods the first two pairs of thoracic legs may also function as food-pushing limbs, but their segments are typically free. In decapods the first two or three pairs serve as maxillipeds, and their segments are fused within the cephalothorax.

The mouthparts generally reflect feeding habits. In flesh eaters and scavengers the mandibular incisors are typically

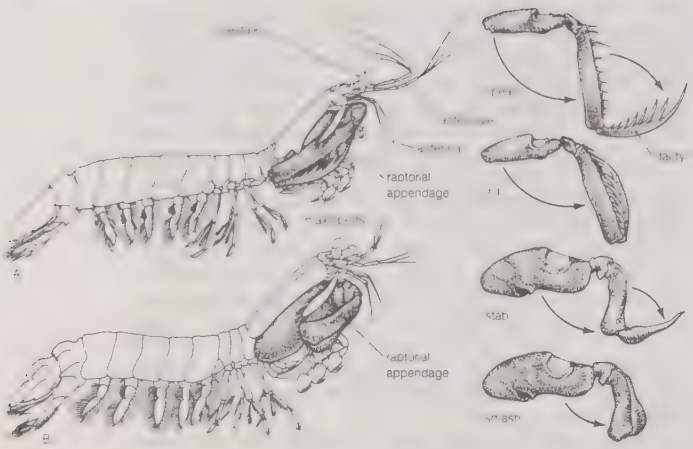

Figure 10: *Raptorial appendages.*
(A) Spearer of the species *Harpiosquilla harpax* has two modes of striking. (Top) In capturing prey, it uses a spearing strike; (bottom) in combat with another stomatopod, spearers usually hit with the dactyls closed. (B) Smasher of the species *Gonodactylus chiragra* uses its raptorial appendages both in combat with other stomatopods and in attacking prey. If the prey is soft-bodied, the smasher will change from a smashing strike to a stabbing one. It also sometimes stabs in intense combat.

large and the plates and palps of the maxillae and maxillipeds are armed with strong spines and cutting edges, whereas the molar is small or lacking. In those species that consume all organic material and in those that consume only plants, the molar is usually strong, with an inner grinding surface. In filter feeders the plates of the maxillules, the maxillae, or both may be enlarged and equipped with a large number of fine-filtering (plumose) setae. Accessory (baler) plates, for directing feeding currents, are often well-developed (*e.g.,* in cumaceans and haustoriid amphipods).

Relationships

Although malacostracans are typically free-living, several taxa, especially among the amphipods, decapods, and isopods, have formed symbiotic, commensal, and even fully parasitic relationships with other invertebrates, fishes, marine mammals, and reptiles. Many decapods, especially porcellanid and xanthid crabs, live permanently in cavities among sponges, corals, and bryozoans. Leucothoid, sebid, and some lysianassid amphipods live within the respiratory and feeding cavities of sponges, tunicates, and anemones. Lafystiid and some lysianassid amphipods, as well as aegid, cymathoid, and immature gnathiid isopods, are external parasites of fish. Cyamid amphipods occur on whales and some hyalid amphipods in the buccal cavities of marine turtles. Epicaridean isopods are fully parasitic on other crustaceans, especially decapods. The body of the host may be much deformed and the body of the parasitic female very much transformed, quite unlike the small, symmetrically segmented, and otherwise normal male.

FORM AND FUNCTION

External features. The chitinous exoskeleton, or cuticle, covering the body and limbs of malacostracans is divided into segments interconnected by strong, flexible membranes, allowing for articulation at the joints. The cuticle is usually soft and thin in small, wormlike, generally subterranean species, in parasitic species, or in the respiratory surfaces of free-living species, where gas exchange with the environment is vital. In large, heavy, mostly carnivorous forms, the cuticle is highly mineralized or impregnated with calcium salts. Such an exoskeleton provides considerable mechanical leverage and protection to the owner.

Malacostracans, like all arthropods, increase in size by molting. This process may take place very rapidly or require several days for completion (in some hard-shelled bottom dwellers). The animals remain in sheltered locations until the exoskeleton is hardened.

Internal features. *The nervous system and sensory organs.* The malacostracan central nervous system consists, in primitive forms, of a ventral nerve cord and ganglia within each body segment. The supraesophageal ganglion innervates the eyes, antennules, and antennae, and the subesophageal ganglion innervates the mouthparts of the head region. In amphipods and anomuran decapods the ganglia of abdominal segments are variously fused. In brachyuran decapods the abdominal and thoracic ganglia are fused into a single central thoracic ganglionic centre.

Eyes

Nearly all surface-dwelling members have pigmented eyes, but these are usually reduced or totally lost in underground and deep-sea species. The eyes of crustaceans are compound and may be composed of thousands of individual facets, or ommatidia. The compound eye of most malacostracans and their advanced larval stages is located on a movable stalk. The overall image is formed by combining the images from many individual ommatidia. Such eyes are called appositional, or mosaic. The compound eye is especially sensitive to movement and has a wide field of vision, often more than 180°, and is of enormous advantage to large, predatory malacostracans.

The eyes of smaller, mainly benthic, nonpredatory malacostracans, such as amphipods, hemicarideans, and isopods, are located on small lobes or flat on the sides of the head. Except in predatory or nocturnal amphipods, the eyes are small and consist of relatively few facets. Light that may strike a large patch of facets is concentrated on one ommatidium. Such eyes provide poor visual acuity. Compound eyes can discriminate colour, initiating changes within skin cells to match the colour of the substratum.

Olfactory hairs, or esthetascs, are used to locate food and recognize other crustaceans and their sexual states. Tactile setae occur generally over the external surfaces and appendages, especially of the antennae, food-gathering limbs, and mouthparts. Tactile hairs are present in the statocysts (organelles of balance) located, for example, in the first peduncular segment of the antennules in amphipods and the superorder Eucarida.

Some decapods and amphipods are sensitive to pressure change. Minute pit sensory organs of the general body surface are suspected receptors. Many decapods and amphipods produce sound by striking (percussion) or rasping (stridulating) or by internal mechanisms. Organs of sound reception include, in brachyurans, the chordotonal organs on the hinges of walking legs. Highly specialized sound and vibration receptors include the antennal calceoli of amphipods, the individual microstructure of which consists of receiving elements arranged serially and attached to the antennal segment by a slender stalk. In more-advanced groups the basal elements are expanded into a cuplike receptacle, and the stalk is distally expanded into a bulla, or resonator. The mechanism of transmission to the brain is unknown since nerve connections have not been discovered. In highly advanced predatory amphipods two types of calceoli are found: one type is used to detect mates (found in males only), and the other is used to detect prey (found in both sexes).

Digestive tract

Digestion and nutrition. The digestive tract of malacostracans consists of an esophagus; a two-chambered foregut; a midgut with outpocketings called digestive glands, or hepatopancreas; and a hindgut, or rectum. The large anterior foregut, or cardiac stomach, occupies much of the posterior aspect of the head and the anterior thoracic body cavity. A constriction separates it from the smaller, more ventral, pyloric stomach that lies in the posterior part of the thorax. Lining the inside of the greatly folded and muscular stomach walls, especially the pyloric portion, are groups or rows of stiff bristles, teeth, and filtering setae known as the gastric mill. The mill is strongly and complexly developed in large decapods, which ingest food quickly and in coarse chunks. The filtering setae are prominent in malacostracans that ingest fine materials or masticate their food throughly with the mouthparts. The macerated and partly digested food works its way through the filtering system of the pyloric stomach into the ceca, or pouches, of the hepatopancreas. There enzyme production and the storage and absorption of food takes place. The digestive secretions depend on the species and diet and include cellulase and chitinase. In stomatopods the

cardiac stomach is large enough to hold the remains of large prey; it opens directly from the mouth without an intervening esophagus. The midgut, or main intestine, may either extend throughout the abdomen, as in lobsters, or be very short, as in crabs. Fecal material is voided through the anus from the short rectum.

Excretion. Malacostracans excrete waste fluids mainly through the ducts of the nephridial glands, which are present in the body segments of the second antennae and the maxillae. The ducts open on the basal segments of those head appendages. Antennal nephridial glands are present in the adult stages of eucaridans, mysidaceans, and amphipods and in the larval stages of stomatopods and hemicarideans. The antennal glands of amphipods are enlarged in freshwater forms but are small in terrestrial species. Maxillary nephridial glands are typical of adult stomatopods, syncaridans, hemicaridans, and isopods. Adult leptostracans have both types of glands. Nephrocytes are present at the bases of thoracic legs and elsewhere in the body of mainly primitive groups. Bathynellaceans have a unique uropodal gland. The sternal gills of amphipods are osmoregulators.

Gills

Respiration. Most large malacostracans respire through gills, which develop as vascularized outgrowths of the first segment of the thoracic legs (epipodal gills). The gills of decapods are in a branchial chamber beneath the carapace, and oxygenated water is funneled through them. The lining of the chamber itself may be soft and vascularized for respiration, as in mysids, thermosbaenaceans, hemicarideans, and peneid shrimps. Land crabs have larger and more vascularized branchial chambers than do aquatic crabs.

The epipodal gills in syncarids and euphausiids are unprotected, since a carapace is either lacking or does not cover the leg bases. In amphipods the gills are usually simple sacs or plates, which in the course of evolution have migrated to the inner side of the legs. The gills are fanned and oxygenated by the pleopods in the ventral tunnel formed by the coxal plates. In stomatopods and isopods gill-like outgrowths of the pleopods or invaginated pseudotracheae (in terrestrial isopods) are the main organs of respiration.

Gas moves across the respiratory surface by diffusion rather than by active transport. Since the chitinous material of the body wall is relatively impermeable, special mechanisms have evolved to boost oxygen uptake. These include increased surface area (dendritic, foliate, pleated, or "double" gills), rich vascularization of respiratory surfaces, ventilating mechanisms (current-directing exopods and baler plates of the maxillae and maxillipeds), and presence in the blood of special respiratory pigments such as hemocyanin.

Blood vascular system. Malacostracans have a more complex open circulatory system than do other crustaceans. The single-chambered heart is enclosed in a pericardial sinus and is located dorsally, above the gut. It is elongate and tubular with several ostia for return flow in primitive forms (orders Leptostraca and Stomatopoda and the superorder Syncarida), but it is short and boxlike with one to two ostia and located in the thorax in advanced forms (decapods). The blood, or hemolymph, is pumped to the head through an aorta and to the gills and locomotor appendages through lateral and ventral arteries. Veins are lacking, and the blood returns to the heart via a series of sinuses.

Endocrine system and hormones. The major neuroendocrine control centre of malacostracans is the X-organ–sinus-gland complex, which lies in the eyestalk or in an equivalent part of the head in which the eyes are sessile. This complex regulates maturation, dispersal of pigments and colour change, and some metabolic processes. The female's ovaries, the male's reproductive glands, the pericardial organs, and the maxillary Y-organs of decapods also produce hormones that function in the molt and reproductive cycles.

Defense and aggression. Malacostracans must defend and fight for food, shelter, space, or mates. Hermit crabs fight over shells to occupy, stomatopods and alpheid shrimps fight over shelters, and terrestrial crabs and tube-building amphipods contest burrows and domiciles. Males may enlarge and embellish some of their appendages at maturity in order to enhance status and indicate sexual intent. Fights to determine status range from highly ritualized displays to death struggles. In decapods the most aggressive fighters are aquatic species, which are well armed, meet infrequently, and compete only occasionally over patchy, ephemeral resources. Terrestrial species, which are more prone to injury, more social, and less limited by availability of resources, exhibit more complex, formalized interactions. Male fiddler crabs attract females by waving the enlarged claw and sending sound signals. The signals establish the identity and intent of the sender. Male ghost crabs build sand pyramids to attract females. Numerous shrimps and some amphipods snap the movable finger of the enlarged claw against the hand as part of threat displays and courtship signals. Many stomatopods have a colour-coded, species-specific eyespot on the claws, which is displayed during posturing. More aggressive species have brighter eyespots. Stomatopods that fight with the same or closely related species reduce the force of their blows or engage in ritualized combat. Relatively docile species are more aggressive when facing more bellicose neighbours. An elaborate set of courtship signals is needed by the male stomatopod to prevent the female from attacking him.

Behaviours

EVOLUTION AND PALEONTOLOGY

The fossil record of the Malacostraca extends from the early Paleozoic era (Early Ordovician epoch, 505 to 478 million years ago) to the present (Figure 11). The early phyllocarids (order Archaeostraca) had a body form which resembled the aquatic branchiocarid arthropods that were diverse in Cambrian seas, 570 to 505 million years ago. Those primitive forms (*e.g.,* Canadaspida) were not directly ancestral, however, since they lacked gnathobasic (chewing) head appendages (*e.g.,* mandibles, maxillae) and other major characteristics of the true Crustacea. Malacostracans share a number of advanced characteristics with the enigmatic class Remipedia, including biramous antennules, a first trunk segment fused to the head, limbs modified as maxillipeds, and paired swimming appendages on all trunk segments posterior to the genital openings.

The first eucaridan malacostracans appeared in the middle Paleozoic (Late Devonian epoch, 374 to 360 million years ago). These were burrowing, lobsterlike, protoglyphaeids with primitive, somewhat pincerlike walking legs and a tail fan with uropods. During the late Paleozoic (Early Carboniferous epoch through Permian period, 360 to 245 million years ago) malacostracans evolved rapidly, apparently in step with the proliferation of coastal vascular plants that formed a major new aquatic food resource. At least 16 new orders arose during that time, some members of moderate size, with both subcheliform and true pincerlike walking legs (*e.g.,* Hoplocarida, Astacidea). In other, mostly smaller, bottom dwellers in brackish to fresh lagoons and estuaries (*e.g.,* Hemicaridea, Syncarida, Mysidacea, Isopoda) the carapace and thoracic respiratory chamber were reduced or lost altogether, the eggs developed directly, within a thoracic brood pouch, and respiration and swimming propulsion became increasingly abdominal. At least eight primitive and unspecialized orders died out by the close of the Permian (*e.g.,* aeschronectid stomatopods, Pygocephalomorpha, Belotelsonidea). During the Mesozoic heyday of the malacostrans, 245 to 66 million years ago, however, an equal number of new orders arose. With the evolution of the anomurans and true crabs during this era, the decapods diversified and grew to large sizes. All major amphipod suborders and infraorders are believed to have evolved by the Jurassic and Cretaceous periods. The isopods had diversified into their nine existing suborders, including those fully parasitic on other crustaceans and fishes. All major continental fresh waters had been widely penetrated via estuaries and coastal groundwaters. Moist lands, then becoming forested with angiosperms, were being occupied by terrestrial isopods and amphipods.

With the subsequent cooling of coastal seas in the Tertiary period, several malacostracan groups (*e.g.,* asellote isopods, lysianassid amphipods, and anomuran decapods)

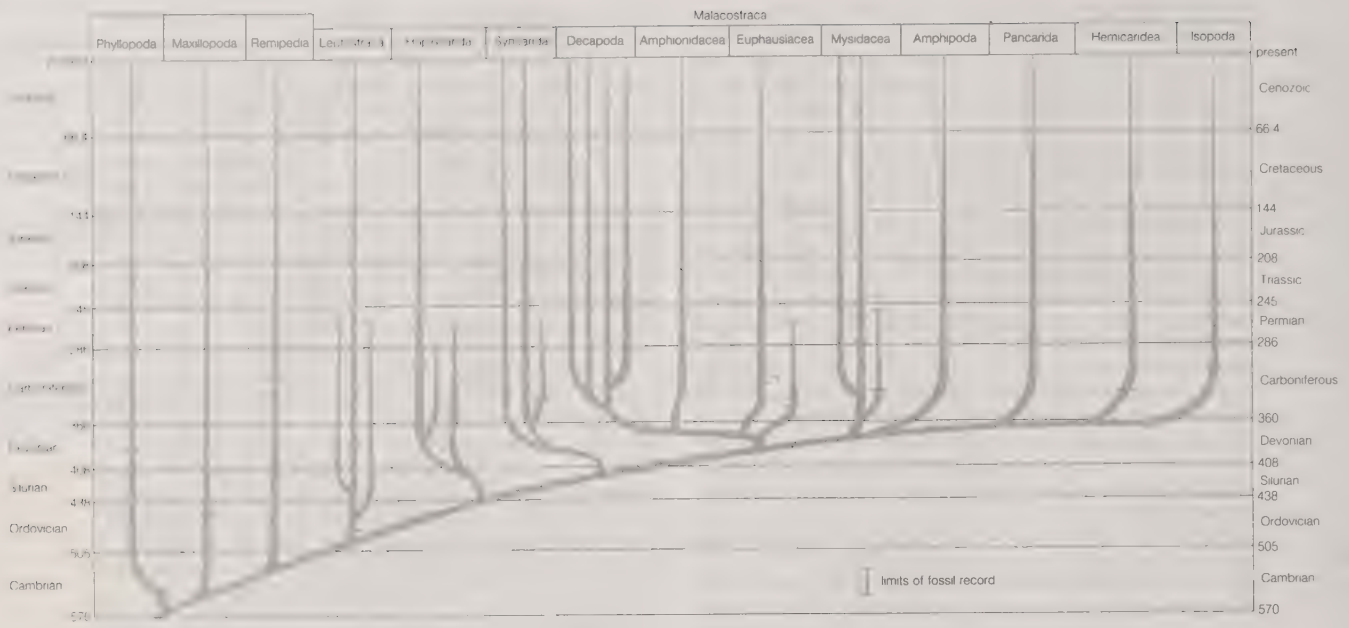

Figure 11: Phylogenetic tree of the Malacostraca.

proliferated in cold-water regions and in the deep sea. The amphipods became associated with mammals and tortoises, which first moved into their ancestral shallows, and coevolved with them to their specialized status as epiparasites of whales and marine turtles. Several malacostracan groups that had proliferated in the warm shallows of late Paleozoic and Mesozoic seas either disappeared or were reduced to a few relict species in deep or anoxic marine habitats (*e.g.,* Lophogastrida, glyphaeid decapods, Leptostraca, Mictacea) or in continental groundwaters (*e.g.,* Syncarida, Spelaeogriphacea, Thermosbaenacea). The isopods, decapods, and amphipods now make up 90 percent of all living malacostracans, with new species still in the process of evolution.

CLASSIFICATION

Diagnostic classification. Malacostracan characters used in diagnosis and classification include type of eye (stalked or sessile), type of antennule (one-, two-, or three-branched, with or without sensory structures), type of antenna (with or without accessory branch, sensory structures), mouthpart structure (including presence or absence of palps, plates, and spines that reflect feeding preferences), carapace (presence or absence, type), anterior segments (degree of fusion with head), anterior limb pairs (degree of modification as maxillipeds, gnathopods), posterior limb pairs (whether single- or double-branched, simple or pincerlike, bearing gills or not), male and female sex ducts (type and position of openings), segmentation (degree of fusion of segments), pleopods (whether annulate or flaplike, sexually modified or not, gill-bearing or not), uropods (present or not, single- or double-branched), and telson (bilobate or platelike, with or without furcae).

Schram (1986) has revised much of the earlier classifications of Calman and others and is generally followed here. A dagger (†) indicates extinct groups.

Annotated classification.

CLASS MALACOSTRACA

Double- or triple-branched antennules; single-branched ambulatory (walking) limbs often equipped with pincers; thoracic and abdominal respiration; terminal body segment with uropods; carapace, variously reduced or lacking, does not cover thoracic limbs; larval development usually of an advanced free-swimming type (*e.g.,* zoea) or often completed within the egg, in which case the first stage is an immature form of the adult; nauplius larva, when present, an advanced maxillopodan type lacking primitive frontal filaments but possessing specialized median eye.

Subclass Phyllocarida

Carapace large, appearing bivalved; thoracic legs with leaflike outer branch; abdomen 7-segmented, lacking uropods; anterior segments with pleopods (swimming legs).

†*Order Archaeostraca.* Early Ordovician to Permian; carapace bivalved and hinged; both antennae with two branches; 6 families.

†*Order Hoplostraca.* Late Carboniferous; carapace short; antennae 2 one-branched, raptorial in form; 1 family.

Order Leptostraca (visored shrimp). Permian to Holocene; carapace large, not hinged; antennae 2 one-branched, slender; terminal abdominal segment with pair of large paddlelike branches; eggs brooded under carapace; marine; on muddy bottoms low in oxygen; intertidal to the deeps; about 15 species in 3 families.

Subclass Hoplocarida

Late Devonian to Holocene; carapace large, not bivalved; rostrum hinged; antennules 3-branched; forward thoracic legs subchelate (clawlike); hind thoracic legs ambulatory (walking) or burrowing; abdomen large; pleopods bearing gills; terminal segment with large tail fan; 3 orders.

†*Order Aeschronectida.* Carboniferous; carapace covers entire thorax; thoracic legs without pincers; terminal body segment elongate; 3 families.

†*Order Palaeostomatopoda.* Late Devonian to Early Carboniferous; carapace covers thorax; anterior thoracic legs with claws; terminal body segment normal; 1 family.

Order Stomatopoda (mantis shrimps). Early Carboniferous, Mesozoic to Holocene; carapace short, exposing thoracic segments 5–8; first 5 pairs of legs clawlike, hind 3 stiltlike; terminal body segment normal; telson unbranched, simple; live in burrows or dens from which they dart forth to smash or spear prey with large clawlike second legs; mainly in tropical marine shallows; 4 superfamilies and 15 families.

Subclass Eumalacostraca

Late Devonian to Holocene; carapace (when present) not bivalved; rostrum fixed; first antenna 2-branched; thoracic legs with slender, many-segmented outer branch and stout, 7-segmented inner branch, often pincerlike, used in walking or food-gathering; 6 (rarely 7) abdominal segments, with pleopods and terminal uropods.

Superorder Syncarida

Late Devonian to Holocene; carapace lacking; thorax and abdomen weakly separated; thoracic legs biramous, bearing gills but without pincer claws; abdomen 6-segmented.

†*Order Palaeocaridacea.* Carboniferous to Permian; first thoracic segment not fused to head; abdominal pleopods 2-branched, flaplike; 4 families.

Order Anaspidacea (torrent shrimps). Triassic to Holocene; first thoracic segment fused to head; pleopods 1-branched, slender, multisegmented; fresh waters of Australia, New Zealand, and South America; 2 suborders and 4 families.

Order Bathynellacea. Permian to Holocene; body minute; wormlike; blind; thorax of 8 segments; legs short, weak; abdomen nearly lacking pleopods; in groundwaters of all continents except Antarctica; 2 families.

Superorder Eucarida

Carapace fused to thorax; thoracic legs usually with gills at bases; eggs usually hatch as free-swimming larvae.

†*Order Belotelsonidea.* Carboniferous; carapace large; thoracic legs 1-branched, simple, without pincers; pleopods flaplike; telson with furcae; 1 family.

Order Euphausiacea (krill). Carboniferous? to Holocene; carapace not covering leg bases; 8 thoracic legs biramous, unspecialized, bearing tuffy gills; telson with furcae; long series of larval stages; marine, pelagic; 2 families.

Order Amphionidacea. Holocene; carapace large; thoracic legs 1-branched; in female, first pleopod expanded under carapace to enclose a brood pouch; deep-swimming, tropical marine.

Order Decapoda (shrimps, lobsters, hermit crabs, crabs). Carapace large, enclosing thorax and gill chamber; inner branch of thoracic legs strong, often pincerlike; first 2–3 pairs smaller, modified as accessory feeding limbs (maxillipeds); uropods and telson usually forming broad tail fan; marine, some freshwater, a few terrestrial; about 9,000 species.

Superorder Pancarida

Order Thermosbaenacea (hot-springs shrimps). Holocene; minute; blind; wormlike; carapace short, forming dorsal brood pounch in female; thoracic legs weak, mostly 2-branched; lacking gills; pleopods weak or lacking; subterranean; about 15 species in 5 families.

Superorder Peracarida

Carapace shortened, attached anteriorly to thorax, or lacking; eggs develop in ventral thoracic brood pouch and hatch as miniature adults.

†*Order Pygocephalomorpha.* Carboniferous to Permian; carapace large, unridged, covering thorax; ventral plates of thorax widening behind; walking legs 6-segmented; abdomen 6-segmented; coastal marine; 4 families.

Order Lophogastrida. Late Carboniferous to Holocene; carapace large, ridged, covering thorax; ventral plates of thorax evenly widened; thoracic legs 7-segmented, weakly modified for grasping prey; abdomen basically 7-segmented; pleopods slender, branches segmented; deep-sea, free swimming; 3 families.

Order Mysidacea. Jurassic to Holocene; carapace short, exposing hind segments; thoracic legs simple, 7-segmented; abdomen 6-segmented; pleopods usually reduced in female, hind pairs modified as claspers in male; brood plates on posterior legs only; marine, freshwater; about 800 species in 4 families.

Order Amphipoda (well shrimps, night shrimps). Eocene to Holocene; carapace lacking; eyes flat on head, not stalked; 7 pairs of 1-branched thoracic legs, each covered basally by a coxal plate; last 5 or 6 pairs bearing gill on inner side; first 2 pairs usually subcheliform (pincerlike); abdomen 6-segmented, with 3 forward pairs of slender, segmented swimmerets and 3 hind pairs of stiff uropods; telson basically bilobed; thoracic brood pouch; eggs hatch as miniature adults; marine, freshwater, one family terrestrial; about 6,200 described species in 4 suborders, 31 superfamilies, and 137 families.

Order Cumacea (tadpole shrimps). Carboniferous to Holocene; head and thorax short, deep; carapace enclosing functional respiratory chamber; abdomen slender; pleopods lacking in female; marine, burrowing in sediments; about 800 species in 9 families.

Order Mictacea. Holocene; body elongate; carapace lacking; respiratory chamber vestigial; pleopods very reduced; marine; 2 families.

Order Spelaeogriphacea. Early Carboniferous to Holocene; body elongate; carapace short; thoracic legs slender, 2–4 with small outer branch; uropods broad; marine and freshwater; 2 families.

Order Tanaidacea (tanaid shrimps). Early Carboniferous to Holocene; body small, cylindrical; eyes on small lobes; carapace short; second thoracic legs large and pincerlike in male; 5 pairs of pleopods; marine, brackish, rarely freshwater; about 350 species in 4 suborders and 21 families.

Order Isopoda (pill bugs, sow bugs, sea slaters). Body flattened dorsoventrally or cylindrical (greatly modified in parasitic members); carapace and respiratory chamber lacking; eyes sessile; 7 pairs of uniramous thoracic legs (some may be pincerlike), lacking gills; leg segment 3 elongate; pleopods broad, often with gills; marine, freshwater, and terrestrial; about 4,500 species in 9 suborders and 100 families.

Critical appraisal. Schram (1986) has divided the Crustacea into four main classes: Remipedia, Malacostraca, Phyllopoda, and Maxillopoda. The Malacostraca are grouped with the last two (higher) crustacean classes in having a clearly demarcated head, thorax, and abdomen, the thorax usually with eight or fewer segments; it is distinct from them but more like the Remipedia in having paired appendages on all body segments.

The relationships of various groups within malacostracan subclasses are constantly undergoing revision in the light of new faunal discoveries and new taxonomic methodology. Schram has revised much of the earlier format (of Calman and others). He eliminated the Calmanian concept of "Peracarida," since it unites groups that are superficially similar rather than naturally closely related, a move with which the classification used here agrees. His format elevates to superorder the Mysidacea (containing orders Mysida, Lophogastrida, and Pygocephalomorpha), the Amphipoda, and the Isopoda and creates a new superorder Hemicaridea (containing orders Cumacea, Spelaeogriphacea, and Tanaidacea, to which this classification also adds the Mictacea). Thus, Schram's elevation of Hoplocarida to subclass level is accepted here, but not his reduction of superorder Syncarida to an order. The classification of the Amphipoda is updated from that of Schram. The mainly fossil subclass Phyllocarida (with two noncrustacean groups removed) is here retained in the Malacostraca (after Dahl). (E.L.B./K.E.C.)

Crustaceans: A major reference on all aspects of the class is DOROTHY E. BLISS (ed.), *The Biology of Crustacea,* 10 vol. (1982–85). ALFRED KAESTNER, *Invertebrate Zoology,* vol. 3 (1970; originally published in German, 2nd ed., 1967), gives an excellent survey of morphology, physiology, embryology, and ecology. Other overviews are provided by the section "Crustacea" in SYBIL P. PARKER (ed.), *Synopsis and Classification of Living Organisms,* vol. 2 (1982), pp. 173–326; RAYMOND C. MOORE (ed.), *Treatise on Invertebrate Palaeontology,* pt. Q, *Arthropoda 3* (1961), and pt. R, *Arthropoda 4,* 2 vol. (1969); and ROBERT D. BARNES, *Invertebrate Zoology,* 5th ed. (1987). ROBERT H. GORE and KENNETH L. HECK (eds.), *Crustacean Biogeography* (1986), is an important discussion on distribution. PATSY A. MCLAUGHLIN, *Comparative Morphology of Recent Crustacea* (1980), gives clear diagrams of external and internal anatomy. FREDERICK R. SCHRAM, *Crustacea* (1986); and FREDERICK R. SCHRAM (ed.), *Crustacean Phylogeny* (1983), include recent theories of crustacean evolutionary relationships.

Branchiopods: H.G. CANNON and F.M.C. LEAK, "The Feeding Mechanism of the Branchiopoda," *Philosophical Transactions of the Royal Society of London,* Series B, 222:267–352 (1933), provides a classical, beautifully illustrated account. A.R. LONGHURST, "A Review of the Notostraca," *Bulletin of the British Museum (Natural History),* 3:1–57 (1955), is a revision of the systematics of the Notostraca and a standard work on the subject. See also G. FRYER, "A New Classification of the Branchiopod Crustacea," *Zoological Journal of the Linnean Society,* 91(4):357–383 (1987).

Cirripedes: CHARLES DARWIN, *A Monograph on the Subclass "Cirripedia,"* 2 vol. (1851–54, reissued as vol. 11–13 of *The Works of Charles Darwin,* 1988), is a comprehensive monograph on the Thoracica and still an important source. PAUL KRÜGER, *Cirripedia,* in *Bronns Klassen und Ordnungen des Teirreichs,* vol. 5, div. 1, fasc. 3, pt. 3 (1940), pp. 1–560, provides an authoritative compilation of knowledge. ALAN J. SOUTHWARD (ed.), *Barnacle Biology* (1987), includes chapters on evolution and genetics, physiology and function, larval biology and settlement, and pollution and fouling. H.G. STUBBINGS, *Balanus Balanoides* (1975), is a comprehensive monograph on the best-known barnacle in the world. Useful journal articles include D.T. ANDERSON, "The Larval Musculature of the Barnacle *Ibla quadrivalvis* Cuvier (Cirripedia, Lepadomorpha)," *Proceedings of the Royal Society of London,* Series B, 231(1264):313–338 (1987), an in-depth comparison of the larval musculature of one of the most primitive pedunculate barnacles with that of a rhizocephalan and balanomorphan; and W. KLEPAL, "*Ibla cumingi* (Crustacea Cirripedia): A Gonochoristic Species (Anatomy, Dwarfing, and Systematic Implications)," *Marine Ecology,* 6(1):47–119 (1985), a study of the gross and fine structure.

Malacostracans: In addition to the general books on crustaceans cited above, see E.L. BOUSFIELD, *Shallow-water Gammaridean Amphipoda of New England* (1973), describing and illustrating the range, ecology, life history, and behaviour of 125 species. (J.Gre./W.A.N./E.L.B./K.E.C.)

Cryptology

Cryptology (from the Greek *kryptós,* "hidden," and *lógos,* "word") is the science of secure (generally secret) communications. This security obtains from legitimate users, the transmitter and the receiver, being able to transform information into a cipher by virtue of a key—*i.e.,* a piece of information known only to them. Although the cipher is inscrutable and often unforgeable to anyone without this secret key, the authorized receiver can either decrypt the cipher to recover the hidden information or verify that it was sent in all likelihood by someone possessing the key. Cryptography (from the Greek *kryptós* and *gráphein,* "to write") is the study of the principles and techniques by which information can be concealed in ciphers and later revealed by legitimate users employing the secret key, but in which it is either impossible or computationally infeasible for an unauthorized person to do so. Cryptanalysis (from the Greek *kryptós* and *analýein,* "to loosen" or "to untie") is the science (and art) of recovering information from ciphers without knowledge of the key. Cryptology is often—and mistakenly—considered a synonym for cryptography and occasionally for cryptanalysis, as in the popular solution of cryptograms or ciphers, but specialists in the field have for years adopted the convention that cryptology is the more inclusive term encompassing both cryptography and cryptanalysis.

Cryptography was concerned initially with providing secrecy for written messages. Its principles apply equally well, however, to securing data flow between computers, to digitized speech, and to encrypting facsimile and television signals. Most communications satellites, for example, routinely encrypt the data flow to and from ground stations to provide both privacy and security for their subscribers. Because of this broadened interpretation of cryptography, the field of cryptanalysis has also been enlarged to include the recovery of information from ciphers concealing any form of data.

This article discusses the basic elements of cryptology, delineating the principal systems and techniques of cryptography as well as the general types and procedures of cryptanalysis. It also provides a concise historical survey of the development of cryptosystems and cryptodevices. For additional information on the encoding and encryption of facsimile and television signals and of computer data, see TELECOMMUNICATIONS SYSTEMS and INFORMATION PROCESSING AND INFORMATION SYSTEMS.

The article is divided into the following sections:

GENERAL CONSIDERATIONS

Because much of the terminology of cryptology dates to a time when written messages were the only things being secured, the source information, even if it is an apparently incomprehensible binary stream of 1s and 0s, as in computer output, is referred to as the plaintext. As noted above, the secret information known only to the legitimate communicants is the key and the transformation of the plaintext under the control of the key into cipher (also called ciphertext or, in older sources, cryptogram) is referred to as encryption or encipherment. The inverse operation, by which a legitimate receiver recovers the concealed information from the cipher using the key, is known as decryption or decipherment.

The fundamentals of codes, ciphers, and authentication. The most frequently confused, and misused, terms in the lexicon of cryptology are *code* and *cipher.* Even experts occasionally employ these terms as though they were synonymous.

A code is simply an unvarying rule for replacing a piece of information (*e.g.,* letter, word, or phrase) with another object, but not necessarily of the same sort. Probably the most widely known code in use today is the American Standard Code for Information Interchange (ASCII). Employed in all personal computers and terminals, it represents 128 characters (and operations such as back space and carriage return) in the form of seven-bit binary numbers—*i.e.,* as a string of seven 1s and 0s. In ASCII a lowercase *a* is always 1100001, an uppercase *A* always 1000001, and so on. In the first quarter of this century, before the telegraph was supplanted by radio communications, elaborate commercial codes that encoded complete phrases into single words (five-letter groups) were developed, so that telegraphers became conversant with such "words" as BYOXO (Are you trying to crawl out of it?), LIOUY (Why do you not answer my question[s]?), AYYLU (not clearly coded, repeat more clearly), or AZQUL (recheck coding and verify). Acronyms are also widely known and used codes, as, for example, RSVP and WASP. Occasionally a code word achieves an independent existence (and meaning) while the original equivalent phrase is forgotten or at least no longer has the precise meaning attributed to the code word—*e.g.,* SNAFU.

ASCII

Difference between ciphers and codes

Ciphers, as in the case of codes, also replace a piece of information (an element of the plaintext that may consist of a letter or word or string of symbols) with another object. The difference is that the replacement is made according to a rule defined by a secret key known only to the transmitter and legitimate receiver(s) in the expectation that an outsider, ignorant of the key, will not be able to invert the replacement to decrypt the cipher. In the past, the blurring of the distinction between codes and ciphers was relatively unimportant. In contemporary communications, however, information is frequently both encoded and encrypted so that it is important to understand the difference. A satellite communications link, for example, may encode information in ASCII characters if it is textual, or pulse-code modulate and digitize it in binary-coded decimal form if it is an analog signal such as speech. It then encrypts the resulting coded data into ciphers by using the Data Encryption Standard (DES; see below). Finally, the cipher stream itself is encoded again, using error-correcting codes for transmission from the ground station to the orbiting satellite. These operations are undone, in reverse order, by the intended receiver to recover the original information.

In the simplest possible example of a true cipher, A wishes to send one of two equally likely messages to B, say, to buy or sell a particular stock. The communication must take place over a party line on which eavesdroppers are listening. It is vital to A's and B's interests that others not be privy to the content of their communication. In order to foil the eavesdroppers, A and B agree in advance as to whether A will tell the truth or lie in what he says to B. Because this decision on their part needs to be unpredictable, they decide by flipping a coin. If heads comes up, A will say "buy" when he wants B to buy and "sell" when he wants B to sell. If tails comes up, however, he will say "buy" when he wants B to sell, and so forth.

		plaintext	
		Buy	Sell
key	H	Buy	Sell
	T	Sell	Buy

Using this encryption/decryption protocol, it should be obvious that the eavesdropper will know no more about the actual (concealed) instruction A sent to B as a result of listening to their telephone communication than he would if he did not listen at all. Such a cryptosystem is defined as *perfect*. The key in this simple example is the knowledge (shared by A and B) of whether A is telling the truth or not. Encryption in this case is the act by A of either lying or not lying as determined by the key, while decryption is the interpretation by B of what A actually meant, not necessarily of what he said.

This example can be extended to illustrate the second function of cryptography: providing a means for B to assure himself that an instruction actually came from A and not from someone impersonating A and that it correctly informs him of A's intentions—*i.e.*, a means of authenticating the message. If an eavesdropper, C, for cryptanalyst, pretends to be B and listens to A's instructions, he could—even though he cannot interpret the cipher to learn A's intentions—cause B to act contrary to A's intention by passing along to B the opposite of what A said. Similarly, C could simply impersonate A and tell B to buy or sell; however, he would not know which action B would take as a result, since he does not know whether A planned to lie or tell the truth. In either event, C would be certain of deceiving B into doing something that A had not requested.

To protect against this sort of deception by outsiders, A and B could use the following encryption/decryption protocol. They secretly flip a coin twice to choose one of four equally likely keys, labeled HH, HT, TH, and TT, with both of them knowing which key has been chosen:

		plaintext	
		Buy	Sell
key	HH	Buy-Buy	Sell-Buy
	HT	Buy-Sell	Buy-Buy
	TH	Sell-Buy	Sell-Sell
	TT	Sell-Sell	Buy-Sell

In this case the ciphers will consist of A's giving two instructions to B, such as Buy-Sell or Sell-Sell, which B can easily interpret to recover A's intended message because he knows the key (row) A used to encrypt the message. However, an outsider attempting to impersonate A will, with probability ½, choose a pair of messages that do not occur in the row corresponding to the key A and B are using; hence, the attempted deception will be detected by B, with probability ½, and the fraudulent message ignored. If C waits and eavesdrops when A communicates a cipher to B, no matter which cipher is used, he will be faced with a choice between two equally likely keys that A and B could be using and with a different cipher that he would have to substitute to have it be accepted by B in either case. Consequently, C's chances of deceiving B are still ½; namely, eavesdropping on A and B's conversation has not improved C's chances of deceiving B.

Clearly in either example, secrecy or authentication with secrecy, the same key cannot be reused. If C learned the cipher by eavesdropping and observed B's response to the cipher, he could deduce the key and thereafter impersonate A with certainty of success. If, however, A and B had chosen as many random keys as they had messages to exchange, the security of the information would have remained the same for all exchanges. When used in this manner, these examples illustrate the vital concept of a onetime key, which is the basis for the only cryptosystems that can be mathematically proved to be cryptosecure (see below). The hot line that links the White House and the Kremlin depends on a onetime key to achieve its cryptosecurity.

One-time key

Applications of cryptology in private and commercial life. Although people may doubt that they have any personal involvement with cryptology, most adults depend on it to protect their interests or rights in several areas. For example, the personal identity number (PIN) that must be entered into an automated teller machine (ATM), along with a bankcard to corroborate that the card is being used by an authorized bearer, may either be stored in the bank's computers in an encrypted form (as a cipher) or be encrypted on the card itself. The transformation used in this type of cryptography is called one-way; *i.e.*, it is easy to compute a cipher given the bank's key and the customer's PIN but computationally infeasible to compute the plaintext PIN from the cipher, even though the key is known. This is to protect the cardholder from being impersonated by someone who has access to the bank's computer files. Similarly, the communications between the ATM and the bank's central computer are encrypted to prevent a would-be thief from tapping into the phone lines and recording the signals sent to the ATM to authorize the dispensing of cash in response to a legitimate user request and then later feeding the same signals to the ATM repeatedly to deceive it into dispensing money illegitimately.

Another example is the means used to prevent forgers from counterfeiting winning lottery tickets. Unlike currency, which typically involves state-of-the-art engraving as well as specially compounded inks and watermarked or tagged papers that make counterfeiting difficult, lottery tickets are simply printed on pasteboard much like the admission tickets used by movie theatres and hence are easily counterfeited if one knows what to print on the ticket. Each ticket, however, has two numbers printed on it—one being the identifying number that will be announced when a winner is selected and the other being an encrypted version of this number. Thus, when the winning number is made known, the would-be counterfeiter is unable to print an acceptable forgery unless he also has successfully cryptanalyzed the lottery's cryptosystem.

The two preceding examples involve only the use of the authentication feature of a cryptosystem, although secrecy is incidental to the communications between the ATM and the bank's central computer. A novel application that involves all aspects of cryptography are "smart" credit cards, which have a microprocessor built into the card itself. Smart credit cards first saw general use in France in 1984 and promise to supplant in large part the simple plastic cards currently being used. Cryptology is essential to the functioning of these cards in several ways. The user must corroborate his identity to the card each time a transaction is made in much the same way that a PIN is used with an ATM. The card and the card reader execute a sequence of encrypted sign-/countersign-like exchanges to verify that each is dealing with a legitimate counterpart. Once this has been established, the transaction itself is carried out in encrypted form to prevent anyone, including the cardholder or the merchant whose card reader is involved, from eavesdropping on the exchange and then later impersonating either party to defraud the system. This elaborate protocol is carried out in such a way that it is transparent to the user, except for the necessity of entering a PIN to initiate the transaction.

There are many other novel areas in which cryptography

plays a role in everyday life. In electronic mail, which has had a pilot test in the United States and was already in operation in France by 1984, the only way to provide an "envelope" for the messages is by some form of encryption. Increasingly, the data bases in which personal tax, income, credit-rating information, and other related data are compiled have become shared resources, remotely accessible to read from or to write into, so that cryptographic protection is vital for safeguarding the rights of the individual. Recognizing the threat to national security posed by breaches in computer-system security and attempts to eavesdrop on telecommunications, the U.S. government has taken steps to counteract the problem. Executive approval in 1984 of National Security Directive 145 led to the establishment of the National Telecommunications and Information Systems Security Committee, whose objective is to provide telephone and computer security for the federal government and its contractors. Clearly, information security—and this generally means cryptographically protected information—is one of the major problems faced by postindustrial society, and as such touches almost every aspect of private and commercial life.

Data security

CRYPTOGRAPHY

Cryptographic systems are generically classified (1) by the mathematical operations through which the plaintext information is concealed using the encryption key—namely, transposition, substitution, or product ciphers in which two such operations are cascaded; (2) according to whether the transmitter and receiver use the same key (symmetric cryptosystem) or different keys (asymmetric [two-key or public-key] cryptosystem); and (3) by whether they produce block or stream ciphers.

Classification of cryptographic systems

The easiest way to describe the techniques on which cryptography depends is to first examine some simple cipher systems and abstract from these examples features that apply to more complex systems. There are two basic kinds of mathematical operations used in cipher systems: transpositions and substitutions. Transpositions rearrange the symbols in the plaintext without changing the symbols themselves. Substitutions replace plaintext elements (symbols, pairs of symbols, etc.) with other symbols or groups of symbols without changing the sequence in which they occur.

Transposition ciphers. In manual systems transpositions are generally carried out with the aid of an easily remembered mnemonic. For example, a popular schoolboy cipher is the "rail fence" in which the plaintext is staggered between rows and the rows are then read sequentially to give the cipher. In a depth two rail fence (two rows) the message WE ARE DISCOVERED SAVE YOURSELF becomes

W A E I C V R D A E O R E F
E R D S O E E S V Y U S L

or

W A E I C V R D A E O R E F E R D S O E E S V Y U S L .

Simple frequency counts on the ciphertext would reveal to the cryptanalyst that letters occur with precisely the same frequency in the cipher and in the plaintext and, hence, that a simple transposition or rearrangement of the letters is involved.

The rail fence is the simplest example of a class of transposition ciphers known as route ciphers, which enjoyed considerable popularity in the early history of cryptology. In general, the elements of the plaintext (usually single letters) are written in a prearranged order (route) into a geometric array (matrix) agreed upon in advance by the transmitter and receiver—typically a rectangle—and then read off by following another prescribed route through the matrix to produce the cipher. The depth two rail fence is a two-row by n-column matrix in which the plaintext is entered sequentially by columns; the encryption route is to read the top row first and then the lower:

Route ciphers

W A E I C V . . .
E R D S O . . .

Clearly both the matrix and the route can be much more complex than those in this example. One form of transposition (permutation) that has been widely used depends on an easily remembered key word for identifying the order (route) in which the columns of a rectangular matrix are to be read. For example, using the key word AUTHOR and ordering the columns by the lexicographic order of the letters in the key word

A	U	T	H	O	R
1	6	5	2	3	4
W	E	A	R	E	D
I	S	C	O	V	E
R	E	D	S	A	V
E	Y	O	U	R	S
E	L	F	A	B	C

yields the cipher

W I R E E R O S U A E V A R B D E V S C A C D O F E S E Y L .

A significant improvement in cryptosecurity can be achieved by reencrypting the cipher obtained from one transposition with another transposition. Because the result (product) of two transpositions is also a transposition, the effect of multiple transpositions is to define a complex route in the matrix, which in itself would be difficult to describe by any simply remembered mnemonic device.

In decrypting a route cipher, the receiver enters the ciphertext symbols into the agreed-upon matrix according to the encryption route and then reads the plaintext according to the original order of entry. The matrix may take the form of a rectangle, trapezoid, hexagon, triangle, or other geometric figure; however, transposition systems in which the keys consist solely in keeping the matrices, starting points, and routes secret are not often employed because of limited security and because manual systems have largely been replaced by automated cipher systems. In the same class also fall systems that make use of perforated cardboard matrices called grilles; descriptions of such systems can be found in most of the older books on cryptography. In contemporary cryptography transpositions serve principally as one of several encryption steps in forming a compound or product cipher.

Substitution ciphers. In substitution ciphers, units of the plaintext (generally single letters or pairs of letters) are replaced with other symbols or groups of symbols, which need not be the same as those used in the plaintext. In Sir Arthur Conan Doyle's "Adventure of the Dancing Men," Sherlock Holmes solved a monoalphabetic substitution cipher in which the ciphertext symbols were stick figures of a human in various dancelike poses.

The simplest of all substitution ciphers are those in which the cipher alphabet is merely a cyclical shift of the plaintext alphabet. Of these, the best known is the Caesar cipher, used by Julius Caesar, in which A is encrypted as D, B as E, and so forth. As many a schoolchild has discovered to his sorrow, cyclical-shift substitution ciphers are not secure. As is pointed out in the section on cryptanalysis (see below), neither is any other monoalphabetic substitution cipher in which a given plaintext symbol is always encrypted into the same ciphertext symbol. Because of the redundancy of the English language, only about 25 symbols of ciphertext suffice to permit the cryptanalysis of monoalphabetic substitution ciphers. The explanation for this weakness is that the frequency distributions of symbols in the plaintext and in the ciphertext are identical, only the symbols having been relabeled. In fact, any given structure or pattern in the plaintext is always preserved intact in the ciphertext, so that the cryptanalyst's task is an easy one.

Caesar cipher

There are two main approaches that have been employed with substitution ciphers to lessen the extent to which structure in the plaintext—primarily single-letter frequencies—survives in the ciphertext. One approach, which culminates in the algebraic cryptosystems of Lester S. Hill, is to encrypt elements of plaintext consisting of two or more symbols; *e.g.*, digraphs and trigraphs. The other is to use several cipher alphabets. When this approach of polyalphabetic substitution is carried to its limit, it results in

onetime keys, or pads, which are the only cryptosystems that can be proved to be cryptosecure.

In manual cryptosystems for encrypting units of plaintext made up of more than a single letter, only digraphs were ever used. By treating digraphs in the plaintext as units rather than as single letters, the extent to which the raw frequency distribution survives the encryption process can be lessened but not eliminated, as letter pairs are themselves highly correlated. The best known digraph substitution cipher is the Playfair invented by Sir Charles Wheatstone but championed at the British Foreign Office by Lyon Playfair, the first Baron Playfair of St. Andrews, whose name the cipher bears. Below is an example of a Playfair cipher, solved by Lord Peter Wimsey in Dorothy L. Sayers' *Have His Carcase.* Here, the mnemonic aid used to carry out the encryption is a 5×5-square matrix containing the letters of the alphabet (I and J are treated as the same letter). A key word, MONARCHY in this example, is filled in first, and the remaining unused letters of the alphabet are entered in their lexicographic order:

Playfair cipher

M	O	N	A	R
C	H	Y	B	D
E	F	G	I/J	K
L	P	Q	S	T
U	V	W	X	Z

Plaintext digraphs are encrypted with the matrix by first locating the two plaintext letters in the matrix. They are (1) in different rows and columns; (2) in the same row; (3) in the same column; or (4) alike. The corresponding encryption (replacement) rules are the following:

1. If the pair of letters are in different rows and columns, each is replaced by the letter that is in the same row but in the other column; *i.e.,* to encrypt WE, W is replaced by U and E by G.
2. A and R are in the same row. A is encrypted as R and R (reading the row cyclically) as M.
3. I and S are in the same column. I is encrypted as S and S as X.
4. If a double letter occurs, a spurious symbol, say Q, is introduced so that the MM in SUMMER would encrypt into NL for MQ and CL for ME.
5. An X is appended to the end of the plaintext if necessary to cause the plaintext to have an even number of letters.

Encrypting the familiar plaintext example using Sayer's Playfair array yields:

```
Plaintext: WE ARE DISCOVERED SAVE YOURSELFX
Cipher:    UG RMK CSXHMUFMKB TOXG CMVATLUIV
```

Figure 1 plots the frequency distribution for the roughly 70,300 alphabetic characters in the present article and, hence, the frequency distribution for any simple substitution cipher of this text and the frequency distribution that results when the text is encrypted using the Playfair key of the example above. If the frequency distribution information were totally concealed in the encryption process, the ciphertext plot of letter frequencies would be flat. The deviation from this ideal is a measure of the tendency of some letter pairs to occur more frequently than others and of the Playfair's row and column correlation of symbols in the ciphertext—the essential structure exploited by a cryptanalyst in solving a Playfair cipher. The loss of a significant part of the plaintext frequency distribution, however, makes a Playfair cipher much harder to cryptanalyze than a monoalphabetic cipher.

The other approach to concealing plaintext structure in the ciphertext involves using several different monoalphabetic substitution ciphers rather than just one; the key specifies which particular substitution is to be employed for encrypting each plaintext symbol. The resulting ciphers, known generically as polyalphabetics, have a long

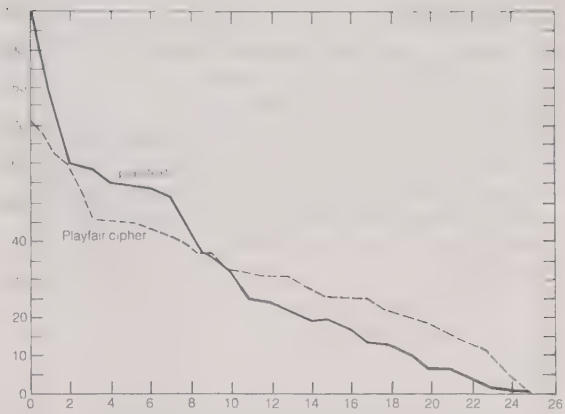

Figure 1: Relative frequency of occurrence of letters in this section and hence in any simple substitution cipher of the text and in a Playfair cipher.

history of usage. The systems differ mainly in the way in which the key is used to choose among the collection of monoalphabetic substitution rules.

The best known polyalphabetics are the simple Vigenère ciphers, named for the 16th-century French cryptographer Blaise de Vigenère. For many years this type of cipher was thought to be impregnable and was known as *le chiffre indéchiffrable.* The procedure for encrypting and decrypting Vigenère ciphers is illustrated in Figure 2.

Vigenère cipher

In the simplest systems of the Vigenère type, the key is a word or phrase that is repeated as many times as required to encipher a message. If the key is DECEPTIVE and the message is WE ARE DISCOVERED SAVE YOURSELF, then the resulting cipher would be

```
Message: WE ARE DISCOVERED SAVE YOURSELF
Key:     DE CEP TIVEDECEPT IVED ECEPTIVE
Cipher:  ZI CVT WQNGRZGVTW AVZH CQYGLMGJ.
```

The cryptanalysis, by Friedrich W. Kasiski, of repeated-key Vigenère ciphers is based on the fact that identical pairings of message and key symbols generate the same cipher symbols. Cryptanalysts look for precisely such repetitions. In the example given above, the group VTW appears twice, separated by six letters, suggesting that the key (*i.e.,* word) length is either three or nine. Consequently, the cryptanalyst would separate the cipher symbols into three and nine monoalphabets and attempt to solve each

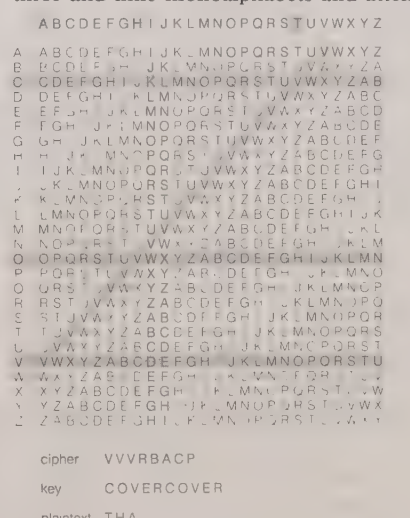

Figure 2: *The Vigenère table.* In encrypting plaintext, the cipher letter is found at the intersection of the column headed by the plaintext letter and the row indexed by the key letter. To decrypt ciphertext, the plaintext letter is found at the head of the column determined by the intersection of the diagonal containing the cipher letter and the row containing the key letter.

of these as a simple substitution cipher. With sufficient ciphertext, it would be easy to solve for the unknown key word. Figure 3 shows the extent to which the raw frequency of occurrence pattern is obscured by encrypting the text of this article using the repeating key DECEPTIVE.

The periodicity of a repeating key exploited by Kasiski can be eliminated by means of the running-key Vigenère cipher. Such a cipher is produced when a nonrepeating text is used for the key. Vigenère actually proposed concatenating the plaintext itself to follow a secret key word in order to provide a running key in what is known as an autokey.

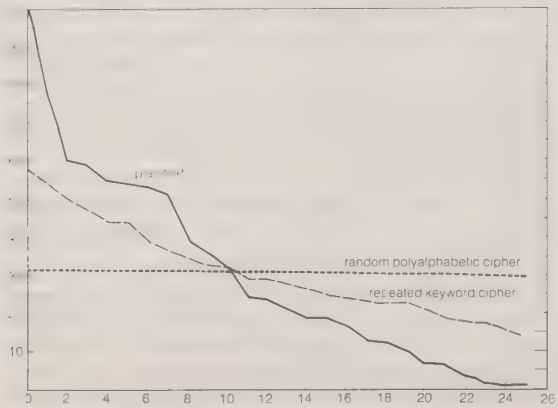

Figure 3: Relative frequency of occurrence of letters in a repeated-key Vigenère cipher—the key word is DECEPTIVE—and in a random polyalphabetic cipher.

Even though running-key or autokey ciphers eliminate periodicity, it is still possible to cryptanalyze them by means of two methods. In one, the cryptanalyst proceeds under the assumption that both the ciphertext and the key share the same frequency distribution of symbols and applies statistical analysis. For example, E enciphered by E would occur in English text with a frequency of ~ 0.0169, and T by T would occur only half as often. The cryptanalyst would, of course, need a much larger segment of ciphertext to solve a running-key Vigenère cipher, but the basic principle is essentially the same as before—*i.e.,* the recurrence of like events yields identical effects in the ciphertext. The second method of solving running-key ciphers is commonly known as the probable-word method. In this approach, words that are thought most likely to occur in the text are subtracted from the cipher. This process is continued until fragments of meaningful key have been obtained. These fragments can then be expanded with either of the two techniques described above. If provided with enough ciphertext, the cryptanalyst can ultimately decrypt the cipher. What is important to bear in mind here is that the redundancy of the English language is high enough that the amount of information conveyed by every ciphertext component is greater than the rate at which equivocation (*i.e.,* the uncertainty about the plaintext that the cryptanalyst must resolve to cryptanalyze the cipher) is introduced by the running key.

In 1918 Gilbert S. Vernam, an engineer for the American Telephone & Telegraph Company (AT&T), introduced the most important of key variants to the Vigenère system. At that time all messages transmitted over AT&T's teleprinter system were encoded in the Baudot Code, a binary code in which a combination of marks and spaces represents a letter, number, or other symbol. Vernam suggested a means of introducing equivocation at the same rate at which it was reduced by redundancy among symbols of the message, thereby safeguarding communications against cryptanalytic attack. He saw that periodicity (as well as frequency information and intersymbol correlation), on which earlier methods of decryption of different Vigenère systems had relied, could be eliminated if a random series of marks and spaces were added to the message being transmitted using a rule that the sum of a pair of like symbols was a mark and that the sum of a pair of unlike symbols was a space (logical sum). The validity of Vernam's idea was confirmed some 30 years later by another AT&T researcher, Claude Shannon, the father of modern information theory.

There was one serious flaw in Vernam's system, however. The system required one symbol of key for each message symbol, which meant that communicants would have to exchange impractically large amounts of the key in advance. The key itself consisted of a punched paper tape that could be read automatically while symbols were typed at the teletypewriter keyboard and encrypted for transmission. This operation was performed in reverse using a copy of the paper tape at the receiving teletypewriter to decrypt the cipher. Vernam initially believed that a short random key could safely be reused many times, but this resulted in a periodicity of the key vulnerable to attack by methods of the type devised by Kasiski. Vernam offered an alternative solution: a key generated by forming the logical sum of two shorter key tapes of m and n binary digits, or bits, where m and n share no common factor other than 1. A bit stream so computed does not repeat until mn bits of key have been produced. This version of the Vernam system was adopted and employed by the U.S. Army until Maj. Joseph O. Mauborgne of the Army Signal Corps demonstrated that a cipher constructed from a key produced by linearly combining two or more short tapes could be decrypted by methods of the sort employed to cryptanalyze running-key ciphers. Mauborgne's work led to the realization that neither the repeating single-key nor the two-tape Vernam–Vigenère system was cryptosecure. Of far greater consequence to modern cryptology—in fact, an idea that remains its cornerstone—was the conclusion drawn by Mauborgne and William F. Friedman that the only type of cryptosystem that is unconditionally secure is a random onetime key. In such a stream cipher, the key is incoherent—*i.e.,* the uncertainty that the cryptanalyst has about each successive key symbol must be no less than the average information content of a message symbol. The dotted curve in Figure 3 indicates that the raw frequency of occurrence pattern is lost when the draft text of this article is encrypted with a random onetime key. The same would be true if digraph or trigraph frequencies were plotted for a sufficiently long ciphertext. In other words, the system is unconditionally secure, not because of any failure on the part of the cryptanalyst to find the right cryptanalytic technique but rather because he is faced with an irresolvable number of choices for the key or plaintext message.

Random onetime key

Product ciphers. In the discussion of transposition ciphers it was pointed out that by cascading (forming the product of) two or more simple transpositions, one could realize an equivalent transposition much harder to specify than the factor transpositions. In the days of manual cryptography this was a useful device for the cryptographer and, in fact, double transposition ciphers on keyword-based rectangular matrices were widely used. There was also some use of a class of product ciphers known as fractionation systems, wherein a substitution was first made from symbols in the plaintext to multiple symbols (usually pairs, in which case the cipher is called a biliteral cipher) in the ciphertext, which was then superencrypted by a transposition. One of the most famous field ciphers of all time was a fractionation system, the ADFGVX cipher employed by the German Army during World War I. This system used a 6×6 matrix to substitution-encrypt the 26 letters and 10 digits into pairs of the symbols A, D, F, G, V, and X. The resulting biliteral cipher was then written into a rectangular array and route encrypted by reading the columns in the order indicated by a key word as illustrated in Figure 4.

Fractionation systems

In spite of the great French cryptanalyst Georges J. Painvin's success in cryptanalyzing critical ADFGVX ciphers in 1918, with devastating effect for the German army in the battle for Paris, the U.S. cryptanalyst Stephen M. Matyas presented, as recently as 1984, new research on the cryptanalysis of ADFGVX ciphers.

Of much greater significance in the history of cryptology is a class of cipher machines generically known as rotor systems. Pneumatic and optical systems have been built, but only the electrical variety has been of value. Typically,

Rotor systems

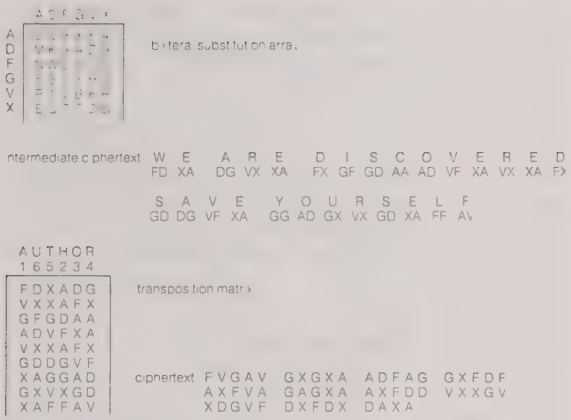

Figure 4: German ADFGVX cipher.

these electrical cipher machines employ wired rotors as a means of generating a multiplicity of substitutions. Such a rotor generally consists of a small disk. On each of the two sides of the rotor are 26 electrical contacts arranged in a circle near its edge. (The normal A–Z alphabet sequence is often engraved on the periphery of the rotor, providing a convenient means of aligning it at specific positions against a benchmark.) The contacts on one side of the rotor are connected by wires in mixed order to the contacts on the opposite side. In this way, an arbitrary set of one-to-one connections (*i.e.*, simple monoalphabetic substitutions) is realized between the two opposite sides of the rotor. A set of these rotors is usually arranged in a stack called a basket; the rotation of each of the rotors in the stack causes the next one to rotate. In some systems, each rotor advances one step in a regular sequence much as the wheels in an odometer advance $^1/_{10}$ of a revolution for every full revolution of its driving wheel. In operation, the rotors in the stack provide an electrical path from contact to contact through all of the rotors. In a straight-through rotor system (Figure 5), closing the key contact on a typewriter-like keyboard sends a current to one of the contacts on the end rotor. The current then passes through the maze of interconnections defined by the remaining rotors in the stack and their relative rotational positions to a point on the output end plate, where it is connected to either a printer or an indicator, thereby producing the cipher equivalent of a plaintext letter.

During World War II an important variation was introduced: the output end plate was a reflector to which 13 pairs of electrical contacts on the end rotor were connected. In this type of arrangement, an electrical current flows through the rotor stack and is then turned back to pass through it a second time. The output is taken from a contact in the same set to which the input was made. Accordingly, if A encrypted to W, then conversely W encrypted to A, for a particular set of rotors and positions. The advantage of this scheme is that when a pair of rotor machines is set to the same starting configuration, plaintext input to one machine generates ciphertext, which when input to the other reproduces the plaintext. The reflector also ensures that the ciphertext symbol is different from the plaintext symbol. The German Enigma cipher machine of World War II made use of this innovation.

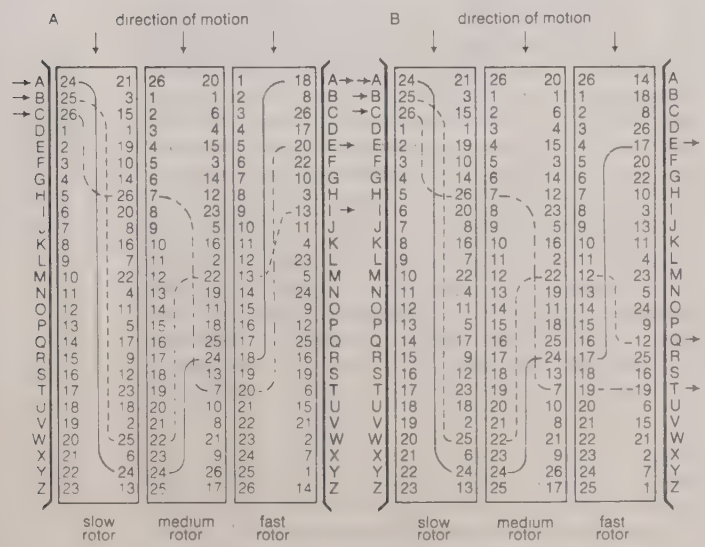

Figure 5: Three-rotor machine with wiring represented by numbered contacts. (A) Position as enciphering is begun. (B) Position after fast rotor has moved one position.

Another type of rotor machine is much more like the Vernam encryption system (see above). Such devices are pin-and-lug machines, and they typically consist of a collection of rotors having a prime number of labeled positions on each rotor. At each position a small pin can be set to an active or inactive position. In operation, all of the rotors advance one position at each step. Therefore, if the active pin settings are chosen appropriately, the machine will not recycle to its initial pin configuration until it has been advanced a number of steps equal to the product of the number of positions in each one of the rotors. Figure 6 shows a machine of this type, the Hagelin M-209 (named for the Swedish engineer Boris Hagelin), which was used extensively by the U.S. military for tactical field communications during World War II. In the M-209 the rotors have 26, 25, 23, 21, 19, and 17 positions, respectively, so that the key period length is 101,405,850. The relationship to the Vernam encryption system is not only through the way in which a lengthy binary sequence of active pin settings in the rotors is achieved by forming the product of six much shorter ones but also in the way a symbol of plaintext is encrypted using the resulting key stream. Just behind the rotors is a squirrel cage consisting of 27 bars on each of which is a pair of movable lugs. Either or both of the lugs can be set in a position to be engaged and moved to the left on each step by a diverter actuated by the presence of an active pin on the corresponding rotor. The result is an effective gear wheel in which the number of teeth is determined by both the active pin settings and the movable lug settings. The number of teeth set determines the cyclical shift between one direct alphabet (plaintext) ABC . . . and a reverse standard alphabet ZYX . . . Thus if no tooth were present, A would encrypt to Z, B to Y, and so forth, while one tooth present would cause A to encrypt to Y, B to Z, etc. This is strictly a Vernam-type encryption—*i.e.*, encryption by subtraction modulo 26 of the key symbol from the plaintext symbol. To decrypt, the ciphertext is processed with the same pin settings that were used to encrypt it but with the cyclical shift set to occur in the opposite direction.

Figure 6: Hagelin design M-209 U.S. cipher machine used for tactical communications during World War II.

The significance of the above historical remarks about

product ciphers and related matters is that they point the way to the most widely adopted and used cipher in the history of cryptography—the Data Encryption Standard (DES).

The Data Encryption Standard. The rapid development of electronic data processing during the 1960s led to the creation of large computer data bases that were routinely communicated or made remotely accessible via resource-sharing networks. Public and private sectors alike soon recognized the need to safeguard both the privacy and the integrity of the stored data. In the United States, for example, the Privacy Act of 1974 and subsequent statutes imposed legal requirements on government agencies and certain government contractors to ensure the confidentiality of records in their possession, and, as banking became more automated and electronic fund transfers mounted into billions of dollars, the potential liability from information misuse in commercial situations created an urgent need for some way of providing information security. As a result, the National Bureau of Standards—after a lengthy evaluation in consultation with the National Security Agency, the cryptologic service of the U.S. government—announced in July 1977 that a Data Encryption Standard was to be implemented in special-purpose electronic devices and to be used in unclassified U.S. government applications for the protection of binary-coded data during transmission and storage in a computer system or network. As a consequence of the certification of the DES by the Bureau of Standards and its continuing support of the cipher in the certification of large-scale integrated (LSI) and very large-scale integrated (VLSI) electronic chips, the DES has become a de facto standard for business and commercial data security as well.

Product block cipher

The DES is a product block cipher in which 16 iterations, or rounds, of the substitution and transposition (permutation) process are cascaded. The block size is 64 bits, so that a 64-bit block of data (plaintext) can be encrypted into a 64-bit cipher at any one time. (A 64-bit block cipher can be decrypted by the DES as well.) The key, which controls the transformation, also consists of 64 bits. Only 56 of these, however, are at the user's disposal; the remaining eight bits are employed for checking parity (the state of being odd or even used as a basis for detecting errors in binary-coded data). Figure 7 is a functional schematic of the sequence of events that occurs in the DES encryption (or decryption) transformation. Subsets of the key bits are designated K_1, K_2, etc., with the subscript indicating the number of the round. The cipher function (substitution and transposition) that is used with the key bits in each round is labeled f. At each intermediate stage of the transformation process, the cipher output from the preceding stage is partitioned into the 32 leftmost bits, L_i, and the 32 rightmost bits, R_i. R_i is transposed to become the left-hand part of the next higher intermediate cipher, L_{i+1}. The right-hand half of the next cipher, R_{i+1}, however, is a complex function of the key and of the entire preceding intermediate cipher. The essential feature to the security of the DES is that f involves a very special nonlinear substitution—*i.e.*, $f(A) + f(B) \neq f(A + B)$—specified by the Bureau of Standards in tabulated functions known as S boxes. This operation results in a 32-bit number, which is logically added to R_i to produce the left-hand half of the new intermediate cipher. This process is repeated, 16 times in all. To decrypt a cipher, the process is carried out in reverse order, with the 16th round being first. The DES process lends itself well to integrated-chip implementation. By 1984 the Bureau of Standards had certified over 35 LSI- and VLSI-chip implementations of the DES, most on single 40-pin chips, some of which operate at speeds of several million bits per second.

The use of the DES algorithm has been made mandatory for all financial transactions of the U.S. government involving electronic fund transfer, including of course those conducted by member banks of the Federal Reserve System. Such transactions must be authenticated in conformance with the American National Standards Standard X9.9, which is written around the DES algorithm.

In a sense the DES is the logical culmination of a long history of development of single-key cryptographic algorithms, and it is this aspect that has been emphasized in the discussion thus far. In another sense, however, the DES is quite different from anything that preceded it. Cryptology has traditionally been a secretive science, so much so that it is only in the last few years that the principles on which the cryptanalysis of the Japanese and German cipher machines of World War II were based have been declassified and released. What is different about the DES is that it is a totally public cryptographic algorithm. Every detail of its operations—enough to permit anyone who wishes to to program it on a microcomputer—is available in published form in Federal Information Processing Standards Publication 46. The paradoxical result is that what is generally conceded to be one of the best cryptographic systems in the history of cryptology is also the least secret.

Key distribution problem. A driving force in the practical use of cryptography is the key distribution problem inherent in single-key cryptosystems. This problem can best be described by means of a simple analogue to encryption/decryption. A and B are to be physically apart and will be able to communicate only by way of intermediaries who will pass along messages, which they may either read or alter. In order to communicate in secret, A and B obtain a strongbox with a double-acting dead bolt on it, so that a key must be used to lock or unlock the box. Locking a message in the box is analogous to encryption and unlocking to decryption. The locked box, containing a secret message, is the analogue of a cipher. If A and B each have a copy of the key and no one else does, then whenever either of them receives a locked box containing a message that person can be confident the message actually came from the other party because only one or the other of them could have locked the box (authentication). By the same token, the sender of the message can be certain that only the intended recipient can open the box (secrecy). This, of course, requires that A and B either meet in person at the time the system is set up to share the secret key or exchange the key via a trusted courier, which is how actual cryptographic keys have traditionally been disseminated. A and B must thereafter protect the key in their possession, because if C, the cryptanalyst, can

gain access to either's key to make a copy he could then lock messages in the box to impersonate A or B or else open the box sent by either party and read the enclosed message. If A or B allows his key to be compromised, however, neither authentication nor secrecy can be relied on thereafter.

Consider a system with only 1,000 subscribers, any two of whom may wish to communicate in secret or be able to verify the source of a message. In this case, A would need to exchange secret keys with 999 other subscribers and would have to protect all 999 keys in his possession in precisely the same way he did the single key he shared with B before. One of these keys would still be shared with B, but B would also need to have 998 other keys to enable him to communicate securely with persons other than A. In short, 499,500 different keys are needed if every pair of subscribers among 1,000 is to be able to communicate securely. Each subscriber would have to exchange secret keys with every one of the 999 other subscribers and then protect the integrity of the 999 keys that he is responsible for. The key distribution problem is that the number of keys required increases proportionate to half the square of the number of users. Furthermore, since the same key is held by both users of any one of the secure data links, say between A and B, A must trust B to protect his key so that A's messages to B are secret and the messages (locked boxes) A receives—purportedly sent by B—are necessarily from B (authentic). In most military and diplomatic communications this latter condition of mutual trust is satisfied; *e.g.,* one embassy, A, can rely on another embassy, B, to protect the cryptographic keys entrusted to its care. In other words, A is not concerned that B may send messages to him and later disavow them as forgeries created by A, nor claim to have received messages from A that he fraudulently created himself. In commercial and business applications, however, these are precisely the major concerns of the users—namely, the customer does not want to give the merchant the ability to create undetectable forgeries in his stead, nor would the merchant accept a system in which the customer could disavow a legitimate draft.

The key distribution problem of single-key cryptography is that the number of secret keys needed increases proportionate to the square of the number of users of the system and that each user must be responsible for the protection of as many keys as there are users (less one). The related problem arising from the symmetry of the cryptographic system is that each user must trust the other users to protect their copies of the keys that he depends on. This is a characteristic of single-key cryptographic systems and not itself part of the key distribution problem.

Two-key cryptography. Continuing with the locked strongbox analogy of the preceding section, assume that the double-acting dead bolt can only be locked with a key that will not unlock it once it has been locked. Assume, too, that it can be unlocked with another key that cannot lock the box. Most importantly, assume that neither of the keys can be re-created from the other. Now consider the 1,000-user system discussed earlier. A makes 999 copies of a locking key to a strongbox for which he keeps and protects the only copy of the unlocking key. He could then distribute the locking keys publicly by passing them out to everyone. Anyone wishing to send A a secret message would be able to lock it in a strongbox with confidence that only A could open the box. In this scheme, for the 1,000-user example, each user would need to have access to 1,000 keys, one of which is his personal decryption (unlocking) key that he must protect (in his own interest) and 999 of which are the other users' publicly exposed locking keys that he can use but need not protect. The total number of keys is only 2,000, in contrast to the 499,500 keys required for the single-key cryptosystem, with everyone having a single secret key and with 1,000 public keys in all. A system of this sort, variously called a two-key, public-key, or asymmetric cryptosystem, largely solves the key distribution problem.

There is, however, an obvious flaw in such a system. When A receives a locked box and opens it with his private unlocking key, he can be certain that only he and the person locking the box are privy to the contents. Yet, he cannot be sure who sent him the locked box, since any user could have locked it by using A's public locking key. The system has preserved secrecy at the expense of forfeiting any capability of authentication. If, on the other hand, A made public the unlocking (decryption) key and kept secret the locking key, any of the users could open a box that A locked, with confidence that only A could have locked it. A would have no way of restricting who opens the box, however. In this case, the ability to authenticate messages has been preserved at the expense of completely giving up secrecy or privacy. The analogy can be profitably extended one step further. If each user had distinct private locking and unlocking keys with publicly exposed matching keys, then A could first lock a message intended for B in a box using A's private locking key and then lock that box inside another box using B's public locking key. Now only B could open the outer box, thus ensuring secrecy. Because the inner box could only have been locked by A, B would be confident of the authenticity of the message. It is this protocol involving iterated encryptions with public and private keys that makes public-key cryptography so attractive for commercial and private applications.

In single-key cryptosystems, the secret encryption and decryption keys K_E and K_D used by the transmitter and receiver, respectively, were either the same or could be easily computed from a knowledge of the other key. In two-key cryptography this is not true. Whereas single-key cryptosystems have been in use for centuries, two-key cryptography is a recent development. In 1976, Whitfield Diffie and Martin E. Hellman proposed a conceptual scheme for this kind of cryptosystem, which they called a public-key cryptosystem, because users could avoid the key distribution problem by simply publishing their encryption keys in a public directory. This was the first discussion of two-key cryptography in the open literature. However, Adm. Bobby Inman, while director of the U.S. National Security Agency, pointed out that two-key cryptography had been discovered at the agency a decade earlier.

Avoiding the key distribution problem

For two-key cryptography to be possible, cryptosystems must be devised with the following properties:

1. It must be easy for the cryptographer to calculate a matched pair of keys K_E and K_D but computationally infeasible (virtually impossible) for a cryptanalyst to recover either key no matter how much text is available.
2. The encryption and decryption operations should be (computationally) easy for legitimate users to carry out.
3. At least one of the keys must be computationally infeasible for the cryptanalyst to recover even when he knows the other key and arbitrarily many matching plaintext and ciphertext pairs.

No cryptosystem so far devised has satisfied all of these conditions, at least not in a provable way. As a consequence, cryptographers have devised cryptographic functions of this sort by starting with a "hard" mathematical problem, such as the knapsack problem or factoring a product of large prime integers, and attempting to make the cryptanalysis of the scheme be equivalent to solving the hard problem. If this can be done, the cryptosecurity of the scheme is at least as good as the underlying mathematical problem is hard to solve.

Knapsack problem

Ralph C. Merkle and Martin E. Hellman have put forth one of the best known proposals for a public-key cryptosystem. They suggest using the knapsack, or subset-sum, problem as the basis for the system. This problem entails determining whether a number can be realized as the sum of some subset of a given collection of weights and, even more importantly, which subset has the desired sum. For example, using the ten weights 14, 28, 56, 82, 90, 132, 197, 284, 341, 455, the figure 515 is realizable in three different ways as a sum while 516 cannot be realized at all. Merkle and Hellman proposed starting with a collection of weights in which each was greater than the sum of all smaller weights. In this case, it is easy to decide whether a given number S can be represented as a sum of a subset of a set of n weights. S is first compared to the largest weight in the set, and if S is larger the weight is in the subset.

If S is smaller, the weight is not in the subset. On each successive step, S less the sum of the weights that have been kept in the subset is compared to the next weight in order of size. The weight is kept in the subset if and only if it is no larger than the difference of S and the sum of the weights already retained. Clearly this finds the subset that sums to S, if any, in only n comparisons.

The cryptographer uses a secret (invertible) transformation to turn such an easy knapsack into a hard one. The legitimate users, however, knowing the secret transformation, could easily invert the hard knapsack back to the easy knapsack. In the Merkle–Hellman scheme, ciphers were to be sums of subsets chosen from the hard knapsack. Decryption was equivalent to finding the identity of the weights used in forming the sum, which was thought to be a very hard problem if one only knew the hard knapsack, but was an easy problem for anyone knowing the secret transformation because then the problem could be solved using the easy knapsack. Unfortunately for the cryptographer, knapsack-based cryptosystems have been shown not to be secure.

Other proposals for basing the cryptosecurity of two-key cryptoalgorithms on the difficulty of taking discrete logarithms or of inverting large linear codes, etc., also have been shown to be cryptanalytically weak—at least for those cases most attractive to cryptography.

RSA cryptoalgorithm

As a result, the main contenders for two-key cryptosystems in the mid-1980s were those whose cryptosecurity derives from the difficulty of factoring large composite integers. The best known of these is the Rivest–Shamir–Adleman (RSA) cryptoalgorithm. In this system a user chooses a pair of prime numbers p and q so large that factoring the product $n = pq$ is beyond all projected computing capabilities. Testing for primality is easy while factoring is very difficult, so that this is easy to do. As of 1984, the consensus was that p and q need to be about 75 decimal digits in size, and so n is roughly a 150-digit number. Since the largest hard numbers that can currently be factored are 80 digits or less in size and the difficulty of factoring grows exponentially with the size of the number, 150 digits appear cryptosecure for the foreseeable future. Having chosen p and q and hence the modulus $n = pq$, the user selects an arbitrary integer K_E less than n and relatively prime to $p-1$ and $q-1$—*i.e.*, so that 1 is the only factor in common between K_E and $(p-1)(q-1)$. This ensures that there is another number K_D, so that the product $K_E \times K_D$ will leave a remainder of 1 when divided by the least common multiple of $(p-1)$ and $(q-1)$. K_D can be easily calculated using the Euclidean algorithm if one knows p and q. If one does not know p and q, it is equally as difficult to find K_D as it is to factor n, which is the basis for the cryptosecurity of the RSA algorithm. K_E and K_D, when chosen in this way, exhibit the following remarkable behaviour. If m is any number less than n, then

$$m^{K_E} \equiv c \pmod{n} \qquad (1)$$

and

$$c^{K_D} \equiv m \pmod{n} \qquad (2)$$

where the mathematical notation is a shorthand for the statement that c is the remainder (cipher) left when m is raised to the K_E power and divided by the modulus n, and conversely that m is the remainder obtained when c is raised to the K_D power and divided by n. This is true for any m less than n where m is the encoded—not encrypted—message. K_E is the encryption key and K_D is the decryption key. There are some constraints on the choice of p and q and of K_E to maximize cryptosecurity, but these are unimportant to understanding the RSA two-key cryptosystem. For example, if $p = 5$ and $q = 11$ so that the $n = 55$, then the least common multiple of $p-1$ and $q-1$ is $20 = 2^2 \cdot 5$. In this case, any key K_E not divisible by 2 or 5 will have a matching key K_D. In particular, let $K_E = 7$ for which $K_D = 3$. If $m = 2$, then $2^7 = 128$, which leaves the remainder (cipher) 18 when divided by 55. Similarly, when the cipher, 18, is raised to the power K_D, $18^3 = 5{,}832$, which leaves the remainder (plaintext) 2 when divided by 55. Similar behaviour would have been observed for any other choice of a number less than 55 or for any other pair of matched exponents (keys), such as $K_E = K_D = 11$.

To implement a secrecy channel using the RSA cryptosystem, user A would publish K_E and n in the public directory but keep secret K_D and p and q (he need not record nor remember p and q). Anyone wishing to send a private message to A would encode it into numbers less than n and calculate c using formula (1). A can calculate m using formula (2), but the presumption—and evidence thus far—is that for almost all ciphers no one else can find m, given c, unless he can also factor n.

Similarly, to implement an authentication channel, A would publish K_D and n and keep K_E (and p and q) secret. To sign a message, A simply appends some agreed-upon numbers to the encoded message and then encrypts the resulting number using the secret K_E to obtain c. Anyone can decrypt c using the public K_D and must conclude, if the agreed-upon numbers are appended, that A originated the cipher, since only he knew K_E and hence could have calculated a cipher that would decrypt to a message with these properties.

Thus far, all proposed two-key cryptosystems exact a high price for this separation of the privacy or secrecy channel from the authentication or signature channel. The greatly increased amount of computation involved in the encryption/decryption process significantly cuts the channel capacity (bits per second of message information communicated). While there exist several single-chip implementations of the DES single-key algorithm that process information at several million bits per second, the throughput of a comparably secure RSA chip—one using roughly a 150-digit modulus—is only a few thousand bits per second. As a result, the main application of two-key cryptography is in hybrid systems. In such a system a two-key algorithm is used necessarily at low speed to avoid the key-distribution problem by exchanging a randomly generated session key to be used with a single-key algorithm at high speed for communication. At the end of the session, this key is discarded and others are generated as the need arises.

Block and stream ciphers. In general, cipher systems transform fixed-size pieces of plaintext into ciphertext. In the older manual systems these pieces were usually single letters or characters or occasionally, as in the Playfair cipher, digraphs, since this was as large a unit as could feasibly be encrypted and decrypted by hand. Systems that operated on trigrams or larger groups of letters were proposed and understood to be potentially securer, but they were never implemented because of the difficulty in manual encryption and/or decryption. In modern single-key cryptography, using the DES, for example, the units of information are often as large as 64 bits or about 13½ alphabetic characters, whereas two-key cryptography based on the RSA algorithm appears to have settled on 512 bits, or about 109 alphabetic characters, as the unit of encryption.

Characteristics of block and stream ciphers

A block cipher breaks the plaintext into blocks of the same size for encryption using a common key: the block size for a Playfair cipher is two letters and for the DES used in electronic codebook mode, 64 bits of binary-encoded plaintext. While a block could consist of a single symbol, normally it is larger.

A stream cipher also breaks the plaintext into units, normally a single character, and then encrypts the i^{th} unit of the plaintext with the i^{th} unit of a key stream. Vernam encryption with a onetime key is an example of such a system, as are rotor cipher machines and the DES used in the output feedback mode to generate a key stream. Stream ciphers depend on the receiver's using precisely the same part of the key stream to decrypt the cipher that was employed to encrypt the plaintext. They thus require that the transmitter's and receiver's key-stream generators be synchronized. This means either that they must be synchronized initially and stay in sync thereafter or that if synchronization is lost the cipher will be decrypted into a garbled form until it can be reestablished. This latter property of self-synchronizing cipher systems results in what is

Letter	Number of occurrences	Frequency	Letter	Number of occurrences	Frequency	Letter	Number of occurrences	Frequency
E	8,915	.127	C	3,188	.045	G	1,113	.016

H	3,452	.049	B	1,173	.017			

known as error propagation, an important parameter in any stream-cipher system.

CRYPTANALYSIS

History abounds with examples of the seriousness of the cryptographer's failure and the cryptanalyst's success. In World War II the Battle of Midway, which marked the turning point of the naval war in the Pacific, was won by the United States largely because cryptanalysis had provided Adm. Chester W. Nimitz with information about the Japanese diversionary attack on the Aleutian Islands and of the Japanese order of attack for Midway. Another famous example of the consequences of a cryptanalytic success was the British cryptanalysis during World War I of a telegram from the German foreign minister, Arthur Zimmermann, to the German minister in Mexico City, Heinrich von Eckardt, laying out a plan to reward Mexico for entering the war as an ally of Germany. This breakthrough caused Pres. Woodrow Wilson of the United States to reverse his earlier opposition to U.S. entry into the war on the side of the Allies, thereby causing that momentous action much sooner than it would have occurred otherwise.

Basic aspects. While cryptography is clearly a science with well-established analytical and synthetic principles, cryptanalysis is as much an art as it is a science. The reason is that success in cryptanalyzing a cipher is as often as not a product of flashes of inspiration, gamelike intuition, and, most importantly, recognition by the cryptanalyst of pattern or structure, at almost the subliminal level, in the cipher. The great U.S. cryptanalyst Herbert O. Yardley described the crucial step in breaking the Japanese ciphers soon after World War I: "Finally one night I awakened at midnight, for I had retired early, and out of the darkness came the conviction that a certain series of two-letter codewords absolutely must equal AIRURANDO (Ireland). The other words danced before me in rapid succession: DOKURITSU (independence), DOITSU (Germany), OWARI (stop)." It is easy to state and demonstrate the principles on which the scientific part of cryptanalysis depends but nearly impossible to convey an appreciation of the art with which the principles are applied.

Cryptanalyzing single-key cryptosystems

Cryptanalysis of single-key cryptosystems depends on one simple fact—namely, that traces of structure or pattern in the plaintext may survive encryption and be discernible in the ciphertext. Take for example the following: in a monoalphabetic substitution cipher in which each letter is simply replaced by another letter, the frequency distribution with which letters occur in the plaintext alphabet and in the ciphertext alphabet is identical. The cryptanalyst can use this fact in two ways: first, to recognize that he is faced with a monoalphabetic substitution cipher and, second, to aid him in selecting the likeliest equivalences of letters to be tried. The Table shows the number of occurrences of each letter in the text of this article, which approximates the raw frequency distribution for most technical material. The following cipher is the encryption of the first sentence of this paragraph using a monoalphabetic substitution:

UFMDHQAQTMGRG BX GRAZTW PWM
UFMDHBGMGHWOG VWDWAVG BA BAW
GRODTW XQUH AQOWTM HCQH HFQUWG
BX GHFIUHIFW BF DQHHWFA RA HCW
DTQRAHWLH OQM GIFJRJW WAUFMDHRBA
QAV SW VRGUWFARSTW RA HCW
URDCWFHWLH.

W occurs 20 times in the cipher, *H* occurs 16, etc. Even the most unskilled cryptanalyst using the frequency data in the Table should have no difficulty in recovering the plaintext and all but four symbols of the key in this case.

It is possible to conceal information about raw frequency of occurrence by providing multiple cipher symbols for each plaintext letter in proportion to the relative frequency of occurrence of the letter; *i.e.,* twice as many symbols for E as for S, etc. The collection of cipher symbols representing a given plaintext letter are called homophones. If the homophones are chosen randomly and with uniform probability when used, the cipher symbols will all occur (on average) equally often in the ciphertext. No less a mathematician than Carl Friedrich Gauss believed that he had devised an unbreakable cipher by introducing homophones. Unfortunately for Gauss and other cryptographers such is not the case, since there are many other persistent patterns in the plaintext that may partially or wholly survive encryption. Digraphs, for example, show a strong frequency distribution: TH occurring most often, about 20 times as frequently as HT, and so forth. With the use of tables of digraph frequencies that partially survive even homophonic substitution, it is still an easy matter to cryptanalyze a random substitution cipher, though the amount of ciphertext needed grows to a few hundred instead of a few tens of letters.

Homophones

If the cipher preserves the breaks between words as they existed in the plaintext, the frequency distribution for starting and ending letters and digrams in words that are all distinct and different from the raw frequency of letter distributions can be used to advantage. Patterns of letters in words such as XYXX where X is the same cipher symbol can only fit a small selection of words such as BIBB, EPEE, LOLL, LULL, and SASS. In the heyday of manual cryptanalysis, volumes of word patterns were compiled. These are only some of the most obvious and easily described patterns whose persistence may provide a clue to the cryptanalyst. In English there are useful correlations between symbols up to eight or nine positions displaced in a word and of course context dependencies over entire sentences, all of which are of potential use to the cryptanalyst.

Types of cryptanalysis. There are three generic types of cryptanalysis characterized by what the cryptanalyst knows: (1) ciphertext only; (2) known ciphertext/plaintext pairs; and (3) chosen plaintext or chosen ciphertext. In the discussion of the preceding paragraphs, the cryptanalyst knew only the ciphertext and general structural information about the plaintext. Often the cryptanalyst either will know some of the plaintext or will be able to guess at, and exploit, a likely element of the text, such as a letter beginning with "Dear Sir" or a computer session starting with "LOG IN." The last category represents the most favourable situation for the cryptanalyst in which he can cause either the transmitter to encrypt a plaintext of his choice or the receiver to decrypt a ciphertext that he chose. Of course, for single-key cryptography there is no distinction between chosen plaintext and chosen ciphertext, but in two-key cryptography it is possible for one of the encryption or decryption functions to be secure against chosen input while the other is vulnerable.

Because of its reliance on "hard" mathematical problems as a basis for cryptoalgorithms and because one of the keys is publicly exposed, two-key cryptography has led to a new type of cryptanalysis that is virtually indistinguishable from research in any other area of computational

mathematics. Unlike the ciphertext attacks or ciphertext/plaintext pairs attacks in single-key cryptosystems, this sort of cryptanalysis is aimed at breaking the cryptosystem by analysis that can be carried out based only on a knowledge of the system itself. Obviously there is no counterpart to this kind of cryptanalytic attack in single-key systems. One of the most attractive schemes for exchanging session keys in a hybrid cryptosystem depended on the ease with which a number (primitive root) could be raised to a power (in a finite field), as opposed to the difficulty of calculating the discrete logarithm. A special-purpose chip to implement this algorithm was produced by a U.S. company, and several others designed secure electronic mail and computer-networking schemes based on the algorithm. In 1983 Donald Coppersmith found a computationally feasible way to take discrete logarithms in precisely those finite fields that had been of greatest cryptographic interest and thereby gave to the cryptanalyst a tool with which to break those cryptosystems. Similarly, the RSA cryptoalgorithm is no securer than the modulus is difficult to factor, so that a breakthrough in factoring would also be a cryptanalytic breakthrough. In 1980 one could factor a difficult 50-digit number at an expense of 1,000,000,000,000 elementary computer operations (add, subtract, shift, and so forth). By 1984 the state of the art in factoring algorithms had advanced to a point where a 75-digit number could be factored in 1,000,000,000,000 operations. If a mathematical advance made it feasible to factor 150 or more digit numbers in the same number of operations, this would make it possible for the cryptanalyst to break several commercial RSA schemes. In other words, the security of two-key cryptography depends on well-defined mathematical questions in a way that single-key cryptography generally did not and conversely equates cryptanalysis to mathematical research in an atypical way.

Factoring algorithms

HISTORY

Early cryptographic systems and applications. People have probably tried to conceal information in written form from the time that writing developed. Examples survive in stone inscriptions, cuneiform tablets, and papyruses showing that the ancient Egyptians, Hebrews, Babylonians, and Assyrians all devised protocryptographic systems both to deny information to the uninitiated and to enhance its significance when it was revealed. The first recorded use of cryptography for correspondence, however, was by the Spartans, who as early as 400 BC employed a cipher device called the scytale for secret communications between military commanders. The scytale consisted of a tapered baton, around which was spirally wrapped a strip of parchment or leather on which the message was written. When unwrapped, the letters were scrambled in order and formed the cipher; however, when the strip was wrapped around another baton of identical proportions to the original, the plaintext reappeared. Thus, the Greeks were the inventors of the first transposition cipher. During the 4th century BC Aeneas Tacticus wrote a work entitled *On the Defense of Fortifications,* one chapter of which was devoted to cryptography, making it the earliest treatise on the subject. Another Greek, Polybius, devised a means of encoding letters into pairs of symbols by a device called the Polybius checkerboard, which is a true biliteral substitution and presages many elements of later cryptographic systems. Similar examples of primitive substitution or transposition ciphers abound in the history of other civilizations. The Romans used monoalphabetic substitution with a simple cyclic displacement of the alphabet. Julius Caesar employed a shift of three positions so that plaintext A was encrypted as D, while Augustus Caesar used a shift of one position so that plaintext A was enciphered as B.

The scytale

The first people to clearly understand the principles of cryptography and to elucidate the beginnings of cryptanalysis were the Arabs. They devised and used both substitution and transposition ciphers and discovered the use of both letter frequency distributions and probable plaintext in cryptanalysis. As a result, by about 1412, al-Kalkashandī could include a respectable, if elementary, treatment of several cryptographic systems in his encyclopaedia *Ṣubḥ al-aʿshā* and give explicit instructions on how to cryptanalyze ciphertext using letter frequency counts complete with lengthy examples to illustrate the technique.

European cryptology dates from the Middle Ages, during which it was developed by the Papal States and the Italian city-states. The earliest ciphers involved only vowel substitution (leaving consonants unchanged). The first European manual on cryptography (*c.* 1379) was a compilation of ciphers by Gabriele de Lavinde of Parma, who served Pope Clement VII. This manual, now in the Vatican archives, contains a set of keys for 24 correspondents and embraces symbols for letters, nulls, and several two-character code equivalents for words and names. The first brief code vocabularies, called nomenclators, were gradually expanded and became the mainstay for several centuries for diplomatic communications of nearly all European governments. In 1470 Leon Battista Alberti published *Trattati in cifra,* in which he described the first cipher disk; he prescribed that the setting of the disk should be changed after enciphering three or four words, thus conceiving of the notion of polyalphabeticity. Giambattista della Porta provided a modified form of square table and the earliest example of a digraphic cipher in *De furtivis literarum notis* (1563). The *Traicté des chiffres* published in 1586 by Blaise de Vigenère contains the square table commonly attributed to him (Figure 2) and descriptions of the first plaintext and ciphertext autokey systems.

First cipher disk

By 1860 large codes were in common use for diplomatic communications, and cipher systems had become a rarity for this application. Cipher systems prevailed, however, for military communications except for high-command communications because of the difficulty of protecting codebooks from capture or compromise in the field. In the early history of the United States, codes were widely used, as were book ciphers. During the Civil War the Federal Army made extensive use of transposition ciphers, in which a key word indicated the order in which columns of the array were to be read and in which the elements were either plaintext words or code word replacements for plaintext. The Confederate Army primarily used the Vigenère cipher and on occasion monoalphabetic substitution. While the Union cryptanalysts solved most of the intercepted Confederate ciphers, the Confederacy in desperation sometimes published Union ciphers in newspapers, appealing for help from readers in cryptanalyzing them.

Developments during World Wars I and II. During the first two years of World War I, the belligerents employed cipher systems almost exclusively for tactical communications; code systems were still used mainly for high-command and diplomatic communications. Figure 8, showing a U.S. Signal Corps cipher disk, points up the lack of sophistication in the field cipher systems. Nevertheless, some complicated cipher systems were used for high-level communications by the end of the war, the most famous of which was the German ADFGVX fractionation cipher.

The communications needs of telegraphy and radio and the maturing of mechanical and electromechanical technology came together in the 1920s to bring about a true

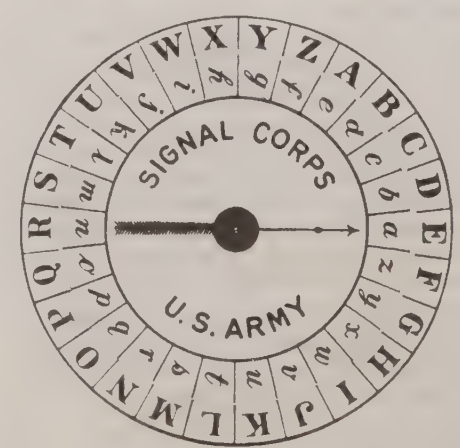

Figure 8: United States Army cipher disk.

revolution in cryptodevices: the development of rotor cipher machines. Although the concept of the rotor had been anticipated in the older mechanical cipher disks, the credit goes to an American, Edward H. Hebern, for first recognizing that by hardwiring a monoalphabetic substitution in the connections from the contacts on one side of an electrical rotor to those on the other side and cascading a collection of such rotors, polyalphabetic substitutions of almost arbitrary complexity could be realized. Hebern also recognized that a permutation in which several letters were shifted by the same amount in the rotor connections, say A to D and B to E, was cryptographically weaker than one in which this partial periodicity was minimized and designed his rotors accordingly. Starting in 1921 and continuing through the next decade, Hebern constructed a series of steadily improving rotor machines that were evaluated by the U.S. Navy and undoubtedly led to the United States' superior position in cryptology as compared to the Axis powers during World War II. The 1920s were marked by a series of challenges by inventors of cipher machines to national cryptologic services and by one service to another, resulting in a steady improvement both of cryptomachines and of cryptanalytic techniques for the analysis of machine ciphers. At almost the same time that Hebern was inventing the rotor cipher machine in the United States, European engineers, notably Hugo A. Koch of The Netherlands and Arthur Scherbius of Germany, independently discovered the rotor concept and designed machines that became the precursors of the best known cipher machine in history, the German Enigma used in World War II (Figure 9). By an indirect path of development, these machines were the stimulus for the TYPEX, the cipher machine employed by the British during World War II. Figure 10 shows a TYPEX with the cover opened to reveal the mechanism of a typical rotor machine. The M-134-C (SIGABA) cipher machine, introduced by the United States during World War II, is shown in Figure 11.

The Japanese cipher machines of World War II have an interesting history linking them to both the Hebern machines and the Enigma. The Washington Conference on naval disarmament (1921–22) had as a primary objective limiting the total tonnage of capital ships (battleships, cruisers, and aircraft carriers) by the major powers—the United States, Great Britain, Japan, France, and Italy. The most difficult problem was the way in which this tonnage was to be allocated among the five countries. The Japanese Foreign Office sent detailed cipher instructions to its ambassador in Washington, D.C., to negotiate for a 10-to-7 U.S.-to-Japanese tonnage ratio, to fall back to 10 to 6.5 if that failed, and only as a last resort to retreat to a lowest acceptable ratio of 10 to 6. In a flash of inspiration Herbert O. Yardley broke the Japanese ciphers (see above), enabling the U.S. representative, Secretary of State Charles Evans Hughes, to press for this lower limit. The Japanese reluctantly accepted the inferior position of 10:10:6:3.3:3.3 (the United States, Britain, Japan, France, and Italy, respectively) laid out in the Five-Powers Treaty. Primarily because of a failure of their cryptography, they had settled for 100,000 tons of shipping less than they might otherwise have obtained, a difference of three capital ships. When Yardley later revealed in 1928 and subsequently published in *The American Black Chamber* the details of the American successes in cryptanalyzing the Japanese ciphers, with the associated costs to Japan, the Japanese government set out to develop the best cryptomachines possible. With this end in mind, it purchased the rotor machines of Hebern and Hagelin and the commercial Enigmas, as well as several other contemporary machines, for study and analysis. In 1930 the Japanese Foreign Office put into service its first rotor machine, which was code-named RED by U.S. cryptanalysts. In 1935–36 the U.S. Army Signal Intelligence Service (SIS) team of cryptanalysts, led by William F. Friedman, succeeded in cryptanalyzing RED ciphers, drawing heavily on its previous experience in cryptanalyzing the machine ciphers produced by the Hebern rotor machines.

It was an ironic twist of fate that the Hebern machines, which were never commercially successful, played such a pivotal role in the design of two widely used rotor machines and in the evolution of the techniques that were

PURPLE cipher machine

vital to the cryptanalysis of the RED ciphers. In 1939 the Japanese introduced a new cipher machine, code-named PURPLE by U.S. cryptanalysts, in which rotors were replaced by telephone stepping switches. Because the replacement of RED machines by PURPLE machines was gradual, providing an enormous number of cribs between the systems to aid cryptanalysts, and because the Japanese had taken a shortcut to avoid the key distribution problem by generating keys systematically, U.S. cryptanalysts were able not only to cryptanalyze the RED ciphers but also to anticipate keys several days in advance. Figure 12 shows one of the functionally equivalent PURPLE cipher machines constructed by Friedman and his SIS associates and used throughout the war to decrypt Japanese ciphers. Apparently no PURPLE machine survived the war. Another Japanese cipher machine code-named JADE was essentially the same as the PURPLE (Figure 13). It differed from the latter chiefly in that it typed Japanese kana characters directly.

The greatest triumphs in the history of cryptanalysis were the Polish and British solution of the German Enigma ciphers and of two teleprinter ciphers, code-named ULTRA, and the American cryptanalysis of the Japanese RED, ORANGE, and PURPLE ciphers, code-named MAGIC. These developments played a major role in the Allies' conduct of World War II. Of the two, the cryptanalysis of the Japanese ciphers is the more impressive technically, because it was a tour de force of cryptanalysis against ciphertext alone. In the case of the Enigma machines, the basic patents had been issued in the United States, commercial machines were widely available, and the rotor designs were known to Allied cryptanalysts from a German code clerk. Although such factors do not diminish the practical importance of the ULTRA intercepts, they did make the cryptanalysis easier.

Figure 12: Functional analogue of the Japanese PURPLE cipher machine, *c.* 1940.

The impact of modern electronics. In the years immediately following World War II, the electronic technology that had been developed in support of radar and the recently discovered digital computer were adapted to cryptomachines. The first such devices were little more than rotor machines in which rotors had been replaced by electronically realized substitutions. The advantage of these electronic rotor machines was speed of operation; the disadvantages were the cryptanalytic weaknesses inherited from mechanical rotor machines and the principle of cyclically shifting simple substitutions for realizing more complex product substitutions.

It was quickly recognized, however, that electronics made possible the practical realization of far more complex cryptographic functions than had previously been feasible. By the 1960s transistors permitted the implementation of complex transformations in special-purpose circuitry. There is a small amount of information in the open literature about the electronic cipher machines used by the various national cryptologic services, but the most reliable indication of cryptographic developments in the period from the final generation of rotor machines—the KL-7 developed by the United States for the North Atlantic Treaty Organization (NATO)—to the appearance of DES and public-key systems in1976 is to be found in commercial equipment. One class of electronic devices representative of contemporary cryptomachine technology is the Fibonacci generator, named for the Fibonacci sequences of number theory. In the classical Fibonacci sequence of integers . . . 21, 13, 8, 5, 3, 2, 1, each succeeding leftmost term is the sum of the two terms to its right; *i.e.*, $x_i = x_{i-1} + x_{i-2}$. By loose analogy, any sequence in which each term is the sum of a collection of earlier terms in fixed (relative) locations is called a Fibonacci sequence. For example, if $x_i = x_{i-1} + x_{i-2} + x_{i-3}$, the sequence . . . 68, 37, 20, 11, 6, 3, 2, 1 . . . results.

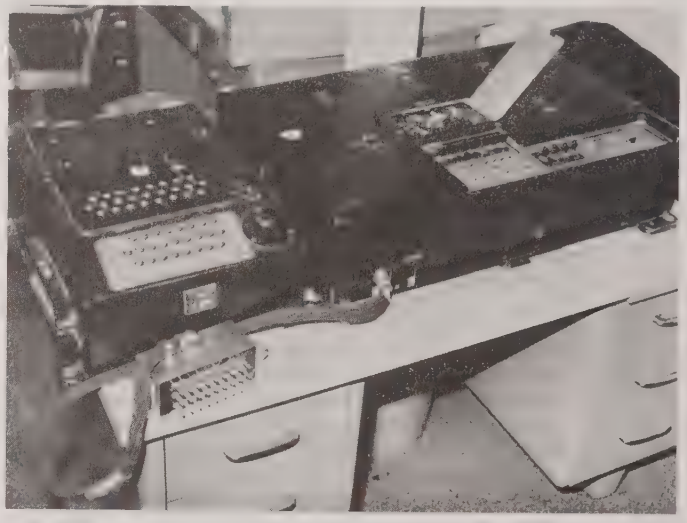

Figure 13: Japanese JADE cipher machine, a member of the PURPLE family of cipher machines.

In an n-stage Fibonacci generator (Figure 14), the contents of the register are shifted right one position at each step—the bit at the extreme right is shifted out and lost—and the new left-hand bit is determined by the logical sum of bits occurring in prescribed locations in the shift register before the shift was made. For example, for $n = 5$ and $x_i = x_{i-1} \oplus x_{i-4} \oplus x_{i-5}$ one obtains the cycle

0 1 0 1 1 1 0 1 1 0 0 0 1 1 1 1 1 0 0 1 1 0 1 0 0 1 0 0 0 0 1,

which is a maximal-length sequence realizable with a five-stage generator. The relevance of Fibonacci generators to cryptography is seen if the sequence is read five bits at a time by successively shifting one bit position to give the scrambled ordering of the integers 1 through 31 (Figure 15), which resembles the scrambled orderings seen

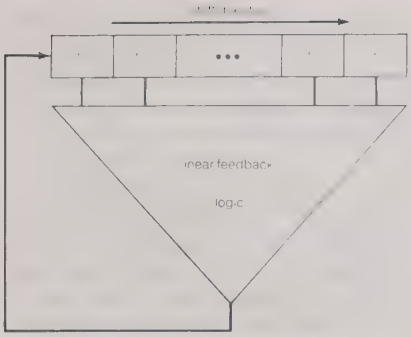

Figure 14: The n-stage Fibonacci generator.

earlier in rotors. If $n = 31$, for instance, the sequence could extend for 2, 147, 483, 647 bits before repeating. If one recalls Claude Shannon's dictum that an ideal cryptomachine should offer the possibility of encrypting any plaintext block into any ciphertext block, a maximal-length linear sequence certainly offers this possibility since every nonzero number occurs somewhere in the cycle. The cryptographic problem is that the combining operation used to determine successive states in the sequence from earlier ones is linear and hence easily invertible, even though the sequence can be 2^n-1 bits in length before repeating. Another problem is how the key is to be used. The obvious choice—namely, to simply use the key to determine the number of steps in the cycle from the plaintext n-tuple to the ciphertext n-tuple—is cryptographically insecure because a known plaintext cryptanalysis would quickly reveal the key. A frequently reinvented solution to this problem has been to use the number found in selected locations of one maximal-length feedback shift register, in which the key is used as the initial register fill, to control the number of steps from the plaintext n-tuple to the ciphertext n-tuple in the cycle of another linear feedback shift register. In schemes of this sort the key register is generally stepped forward to hide the key itself before any encryption of plaintext is carried out and then advanced sufficiently many steps between encryptions to ensure diffusion of the keying variables. To encrypt an n-bit block of plaintext, the text is loaded into the main shift register and the machine stepped through a specified number of steps, normally a multiple of the number of bits in the key, sufficient to diffuse the information in the plaintext and in the key over all positions in the resulting ciphertext. To decrypt ciphertext, it is necessary to have an inverse combiner function or for the original encryption function to be involutory—*i.e.*, for the encryption of the cipher to be the plaintext again. It is not difficult to design the feedback logic to make an involutory machine, which, when filled with a block of ciphertext and reencrypted, will result in the register's containing the original plaintext. Pictorially, the machine has simply retraced its steps in the cycle(s). Linearity in the logic, though, is a powerful aid to the cryptanalyst, especially if a matched plaintext/ciphertext attack is possible.

Maximal-length feedback shift register

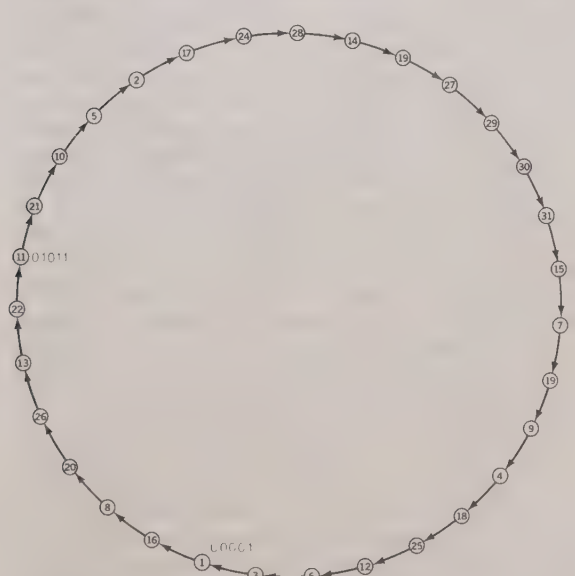

Figure 15: A maximal-length sequence produced by a five-stage Fibonacci generator.

With a slight modification, this approach constitutes the basis of several commercially available cryptographic devices that function in a manner quite similar to the pin-and-lug cipher machines previously described. One such cryptomachine has six maximal-length linear feedback shift registers in which the stepping is controlled by another shift register; the contents of the latter are used to address a (nonlinear) lookup table defined by keys supplied by the user.

As a result, cryptographers have devised a number of nonlinear feedback logics that possess such desirable properties as diffusion of information (to spread the effects of small changes in the text) and large-cycle structure (to prevent exhaustive search) but which are computationally infeasible to invert working backward from the output sequence to the initial state(s), even with many pairs of matched plaintext/ciphertext. The nonlinear feedback logic, used to determine the next bit in the sequence, can be employed in much the same way as linear feedback logic. Nonlinear systems that also satisfy the necessary conditions for invertibility so as to enable the receiver to decrypt the cipher always break up into still very large subcycles. The complicating effect of the key on the ciphertext in nonlinear logics, however, greatly contributes to the difficulty faced by the cryptanalyst. It is generally accepted that no purely cryptanalytic breaks of the cryptoalgorithms developed by the national cryptologic services of the major powers have occurred in recent years, nor are they apt to occur, as a result of the advances in cryptology that have taken place since World War II.

Nonlinear feedback logic

BIBLIOGRAPHY. DAVID KAHN, *The Codebreakers* (1967), also available in an abridged ed. with the same title (1973), is a comprehensive and meticulously researched history of classical single-key cryptology. A comprehensive treatment of current single-key and two-key, or public-key, cryptography can be found in GUSTAVUS J. SIMMONS (ed.), *Contemporary Cryptology: The Science of Information Integrity* (1992), a collection of papers surveying all aspects of current cryptographic practice written by major contributors to the field. Modern texts in cryptology accessible to the general reader include WŁADYSŁAW KOZACZUK, *Enigma: How the German Machine Cipher Was Broken, and How It Was Read by the Allies in World War Two* (1984; originally published in Polish, 1979), an important contribution covering the role played by a team of Polish cryptologists in breaking Enigma; DAVID KAHN, *Seizing the Enigma: The Race to Break the German U-Boat Codes, 1939–1943* (1991), a well-researched study; RONALD LEWIN, *The American Magic: Codes, Ciphers, and the Defeat of Japan* (also published as *The Other Ultra,* 1982), the details and history of the Magic code-breaking machine; DOROTHY ELIZABETH ROBLING DENNING, *Cryptography and Data Security* (1982); GILLES BRASSARD, *Modern Cryptology* (1988), a useful introductory study particularly for those with a background in computer science; and DOMINIC WELSH, *Codes and Cryptography* (1988), by a mathematician. Classical literature of the field includes LUIGI SACCO, *Manual of Cryptography* (1938, reissued 1977; originally published in Italian, 2nd ed., rev. and enlarged, 1936), at one time described by Kahn as "the world's finest unclassified book on cryptology"; MARCEL GIVIERGE, *Course in Cryptography* (1934, reissued 1978; originally published in French, 1925); and most of the manuals written by the great U.S. cryptanalyst WILLIAM F. FRIEDMAN: *Elements of Cryptanalysis* (1976), and *History of the Use of Codes* (1977), are representative works. The most recent information about developments in cryptology is found in *Journal of Cryptology* (3 times/yr.), devoted entirely to the subject; and *Advances in Cryptology* (annual), which can be highly recommended. (G.J.Si.)

The Concept and Components of Culture

Culture may be defined as behaviour peculiar to *Homo sapiens*, together with material objects used as an integral part of this behaviour; specifically, culture consists of language, ideas, beliefs, customs, codes, institutions, tools, techniques, works of art, rituals, ceremonies, and so on. The existence and use of culture depends upon an ability possessed by man alone. This ability has been called variously the capacity for rational or abstract thought, but a good case has been made for rational behaviour among subhuman animals, and the meaning of abstract is not sufficiently explicit or precise. The term symboling has been proposed as a more suitable name for man's unique mental ability, consisting of assigning to things and events certain meanings that cannot be grasped with the senses alone. Articulate speech—language—is a good example. The meaning of the word *dog* is not inherent in the sounds themselves; it is assigned, freely and arbitrarily, to the sounds by human beings. Holy water, "biting one's thumb" at someone (*Romeo and Juliet*, Act I, scene 1), or fetishes are other examples. Symboling is a kind of behaviour objectively definable and should not be confused with symbolizing, which has an entirely different meaning.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 512 and 513.

This article is divided into the following sections:

The concept of culture

VARIOUS DEFINITIONS OF CULTURE

What has been termed the classic definition of culture was provided by the 19th-century English anthropologist Edward Burnett Tylor in the first paragraph of his *Primitive Culture* (1871):

> Culture . . . is that complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities and habits acquired by man as a member of society.

In *Anthropology* (1881) Tylor made it clear that culture, so defined, is possessed by man alone. This conception of culture served anthropologists well for some 50 years. With the increasing maturity of anthropological science, further reflections upon the nature of their subject matter and concepts led to a multiplication and diversification of definitions of culture. In *Culture: A Critical Review of Concepts and Definitions* (1952), U.S. anthropologists A.L. Kroeber and Clyde Kluckhohn cited 164 definitions of culture, ranging from "learned behaviour" to "ideas in the mind," "a logical construct," "a statistical fiction," "a psychic defense mechanism," and so on. The definition—or the conception—of culture that is preferred by Kroeber and Kluckhohn and also by a great many other anthropologists is that culture is an abstraction or, more specifically, "an abstraction from behaviour."

These conceptions have defects or shortcomings. The existence of behavioral traditions—that is, patterns of behaviour transmitted by social rather than by biologic hereditary means—has definitely been established for nonhuman animals. "Ideas in the mind" become significant in society only as expressed in language, acts, and objects. "A logical construct" or "a statistical fiction" is not specific enough to be useful. The conception of culture as an abstraction led, first, to a questioning of the reality of culture (inasmuch as abstractions were regarded as imperceptible) and, second, to a denial of its existence; thus, the subject matter of nonbiological anthropology, "culture," was defined out of existence, and without real, objective things and events in the external world there can be no science.

Kroeber and Kluckhohn were led to their conclusion that culture is an abstraction by reasoning that if culture is behaviour it, ipso facto, becomes the subject matter of psychology; therefore, they concluded that culture "is an abstraction from concrete behavior but is not itself behavior." But what, one might ask, is an abstraction of a marriage ceremony or a pottery bowl, to use Kroeber and Kluckhohn's examples? This question poses difficulties that were not adequately met by these authors. A solution was perhaps provided by Leslie A. White in the essay "The Concept of Culture" (1959). The issue is not really whether culture is real or an abstraction, he reasoned; the issue is the context of the scientific interpretation.

Importance of the context

When things and events are considered in the context of their relation to the human organism, they constitute behaviour; when they are considered not in terms of their relation to the human organism but in their relationship to one another, they become culture by definition. The mother-in-law taboo is a complex of concepts, attitudes, and acts. When one considers them in their relationship to the human organism—that is, as things that the organism does—they become behaviour by definition. When, however, one considers the mother-in-law taboo in its relationship to the place of residence of a newly married couple, to the customary division of labour between the sexes, to their respective roles in the society's mode of

subsistence and offense and defense, and these in turn to the technology of the society, the mother-in-law taboo becomes, again by definition, culture. This distinction is precisely the one that students of words have made for many years. When words are considered in their relationship to the human organism—that is, as acts—they become behaviour. But when they are considered in terms of their relationship to one another—producing lexicon, grammar, syntax, and so forth—they become language, the subject matter not of psychology but of the science of linguistics. Culture, therefore, is the name given to a class of things and events dependent upon symboling (*i.e.,* articulate speech) that are considered in a kind of extra-human context.

Universalist approaches to culture and the human mind. Culture, as noted above, is due to an ability possessed by man alone. The question of whether the difference between the mind of man and that of the lower animals is one of kind or of degree has been debated for many years, and even today reputable scientists can be found on both sides of this issue. But no one who holds the view that the difference is one of degree has adduced any evidence to show that nonhuman animals are capable, to any degree whatever, of a kind of behaviour that all human beings exhibit. This kind of behaviour may be illustrated by the following examples: remembering the sabbath to keep it holy, classifying one's relatives and distinguishing one class from another (such as uncles from cousins), defining and prohibiting incest, and so on. There is no reason or evidence that leads one to believe that any animal other than man can have or be brought to any appreciation or comprehension whatever of such meanings and acts. There is, as Tylor argued long ago, a "mental gulf that divides the lowest savage from the highest ape" (*Anthropology*).

Symboling

In line with the foregoing distinction, human behaviour is to be defined as behaviour consisting of, or dependent upon, symboling rather than upon anything else that *Homo sapiens* does; coughing, yawning, stretching, and the like are not human.

Next to nothing is yet known about the neuroanatomy of symboling. Man is characterized by a very large brain, considered both absolutely and relatively, and it is reasonable—and even obligatory—to believe that the central nervous system, especially the forebrain, is the locus of the ability to symbol. But how it does this and with what specific mechanisms remain to be discovered. One is thus led to the conclusion that at some point in the evolution of primates a threshold was reached in some line, or lines, when the ability to symbol was realized and made explicit in overt behaviour. There is no intermediate stage, logical or neurological, between symboling and nonsymboling; an individual or a species is capable of symboling, or he or it is not. The life of Helen Keller makes this clear: when, through the aid of her teacher, Anne Sullivan, Keller was enabled to escape from the isolation to which her blindness and deafness had consigned her and to effect contact with the world of human meanings and values, the transformation was instantaneous.

Evolution of "minding." But even if almost nothing is known about the neuroanatomy of symboling, a great deal is known about the evolution of mind (or "minding," if mind is considered as a process rather than a thing), in which one finds symboling as the characteristic of a particular stage of development. The evolution of minding can be traced in the following sequence of stages. First is the simple reflexive stage, in which behaviour is determined by the intrinsic properties of both the organism and the thing reacted to—for example, the contraction of the pupil of the eye under increased stimulation by light. Second is the conditioned reflex stage, in which the response is elicited not by properties intrinsic in the stimulus but by meanings that the stimulus has acquired for the responding organism through experience—for example, Pavlov's dog's salivary glands responding to the sound of a bell. Third is the instrumental stage, as exemplified by a chimpanzee knocking down a banana with a stick. Here the response is determined by the intrinsic properties of the things involved (banana, stick, chimpanzee's neurosensory-muscular system); but a new element has been introduced into behaviour, namely, the exercise of control by the reacting organism over things in the external world. And, finally, there is the symbol stage, in which the configuration of behaviour involves nonintrinsic meanings, as has already been suggested.

Increased security and expanse of life

These four stages exhibit a characteristic of the evolution of all living things: a movement in the direction of making life more secure and enduring. In the first stage the organism distinguishes between the beneficial, the injurious, and the neutral, but it must come into direct contact with the object or event in question to do so. In the second stage the organism may react at a distance, as it were—that is, through an intermediate stimulus. The conditioned reflex brings signs into the life process; one thing or event may serve as an indication of something else—food, danger, and so forth. And, since anything can serve as a sign of anything else (a green triangle can mean food, sex, or an electric shock to the laboratory rat), the reactions of the organism are emancipated from the limitations that stage one imposes upon living things, namely, the intrinsic properties of things. The possibility of obtaining life-sustaining things and of avoiding life-destroying things is thus much enhanced, and the security and continuity of life are correspondingly increased. But in stage two the organism still plays a subordinate role to the external world; it does not and cannot determine the significance of the intermediary stimulus: the bark of a distant dog to the rabbit or the sound of the bell to Pavlov's dog. This meaning is determined by things and events in the external world (or in the laboratory by the experimenter). In stages one and two, therefore, the organism is at the mercy of the external world in this respect.

In the third stage the element of control over environment is introduced. The ape who obtains food by means of a stick (tool) is not subordinate to his situation. He does not merely undergo a situation; he dominates it. His behaviour is not determined by the juxtaposition of things and events; on the contrary, the juxtaposition is determined by the ape. He is confronted with alternatives, and he makes choices. The configuration of behaviour in stage three is constructed within the dynamic organism of the ape and then imposed upon the external world.

The evolution of minding is a cumulative process; the achievements of each stage are carried on into the succeeding one or ones. The fourth stage reintroduces the factor of nonintrinsic meanings to the advances made in stages two and three. Stage four is the stage of symboling, of articulate speech. Thus, one observes two aspects of the evolution of minding, both of which contribute to the security and survivability of life: the emancipation of behaviour from limitations imposed upon it by the external world and increased control over the environment. To be sure, neither emancipation nor control becomes complete, but quantitative increase is significant.

Evolution of culture. The direction of biologic evolution toward greater expansion and security of life can be seen from another point of view: the advance from instinctive behaviour (*i.e.,* responses determined by intrinsic properties of the organism) to learned and freely variable behaviour, patterns of which may be acquired and transmitted from one individual and generation to another, and finally to a system of things and events, the essence of which is meanings that cannot be comprehended by the senses alone. This system is, of course, culture, and the species is the human species. Culture is a man-made environment, brought into existence by the ability to symbol.

Once established, culture has a life of its own, so to speak; that is, it is a continuum of things and events in a cause and effect relationship; it flows down through time from one generation to another. Since its inception 1,000,000 or more years ago, this culture—with its language, beliefs, tools, codes, and so on—has had an existence external to each individual born into it. The function of this external, man-made environment is to make life secure and enduring for the society of human beings living within the cultural system. Thus, culture may be seen as the most recent, the most highly developed means of promoting the security and continuity of life, in a series that began with the simple reflex.

Absence of culture in primate societies

Society preceded culture; society, conceived as the interaction of living beings, is coextensive with life itself. Man's immediate prehuman ancestors had societies, but they did not have culture. Studies of monkeys and apes have greatly enlarged scientific knowledge of their social life—and, by inference, the scientific conception of the earliest human societies. Data derived from paleontological sources and from accumulating studies of living, nonhuman primates are now fairly abundant, and hypotheses derived from these are numerous and varied in detail. A fair summary of them may be made as follows: The growth of the primate brain was stimulated by life in the trees, specifically, by eye-hand coordinations involved in swinging from limb to limb and by manipulating food with the hands (as among the insectivorous lemurs). Descent to the ground, as a consequence of deforestation or increase in body size (which would tend to restrict arboreal locomotion and increase the difficulty of obtaining enough food to supply increased need), and the assumption of erect posture were other significant steps in biologic evolution and the eventual emergence of culture. Some theories reject the arboreal stage in man's evolutionary past, but this does not seriously affect the overall conception of his development.

The Australopithecines of Africa, extinct manlike higher primates about which reliable knowledge is very considerable today, exemplify the stage of erect posture in primate evolution. Erect posture freed the arms and hands from their earlier function of locomotion and made possible an extensive and versatile use of tools. Again, the eye-hand-object coordinations involved in tool using stimulated the growth of the brain, especially the forebrain. It is not possible to determine on the basis of paleontological evidence the precise point at which the ability to symbol (specifically, articulate speech) was realized, as expressed in overt behaviour. It is believed by some that man's prehuman ancestors used tools habitually and that habit became custom through the transmission of tool using from one generation to another long before articulate speech came into being. In fact, some theorists hold, the customary use of tools became a powerful stimulus in the development of a brain that was capable of symboling or articulate speech.

Immediate effects of symboling

The introjection of symboling into primate social life was revolutionary. Everything was transformed, everything acquired new meaning; the symbol added a new dimension to primate—now human—existence. An ax was no longer merely a tool with which to chop; it could become a symbol of authority. Mating became marriage, and all social relationships between parents and children and brothers and sisters became moral obligations, duties, rights, and privileges. The world of nature, from the stones beside the path to the stars in their courses, became alive and conscious spirits. "And all that I beheld respired with inward meaning" (Wordsworth). The anthropoid had at last become a man.

Relativist approaches to sociocultural systems. Thus far in this article, culture has been considered in general, as the possession of all mankind. Now it is appropriate to turn to particular cultures, or sociocultural systems. Human beings, like other animal species, live in societies, and each society possesses culture. It has long been customary for ethnologists to speak of Seneca culture, Eskimo culture, North American Plains culture, and so on—that is, the culture of a particular society (Seneca) or an indefinite number of societies (Eskimo) or the cultures found in or characteristic of a topographic area (the North American Plains). There is no objection to this usage as a convenient means of reference: "Seneca culture" is the culture that the Seneca tribe possesses at a particular time. Similarly, Eskimo culture refers to a class of cultures, and Plains culture refers to a type of culture. What is needed is a term that defines culture precisely in its particular manifestations for the purpose of scientific study, and for this the term sociocultural system has been proposed. It is defined as the culture possessed by a distinguishable and autonomous group (society) of human beings, such as a tribe or a modern nation. Cultural elements may pass freely from one system to another (cultural diffusion), but the boundary provided by the distinction between one system and another (Seneca, Cayuga; United States, Japan) makes it possible to study the system at any given time or over a period of time.

Every human society, therefore, has its own sociocultural system: a particular and unique expression of human culture as a whole. Every sociocultural system possesses the components of human culture as a whole—namely, technological, sociological, and ideological elements. But sociocultural systems vary widely in their structure and organization. These variations are attributable to differences among physical habitats and the resources that they offer or withhold for human use; to the range of possibilities inherent in various areas of activity, such as language or the manufacture and use of tools; and to the degree of development. The biologic factor of man may, for purposes of analysis and comparison of sociocultural systems, be considered as a constant. Although the equality or inequality of races, or physical types, of mankind has not been established by science, all evidence and reason lead to the conclusion that, whatever differences of native endowment may exist, they are insignificant as compared with the overriding influence of the external tradition that is culture.

CULTURE AND PERSONALITY

The powerful influence of culture

Since the infant of the human species enters the world cultureless, his behaviour—his attitudes, values, ideals, and beliefs, as well as his overt motor activity—is powerfully influenced by the culture that surrounds him on all sides. It is almost impossible to exaggerate the power and influence of culture upon the human animal. It is powerful enough to hold the sex urge in check and achieve premarital chastity and even voluntary vows of celibacy for life. It can cause a person to die of hunger, though nourishment is available, because some foods are branded unclean by the culture. And it can cause a person to disembowel or shoot himself to wipe out a stain of dishonour. Culture is stronger than life and stronger than death. Among subhuman animals, death is merely the cessation of the vital processes of metabolism, respiration, and so on. In the human species, however, death is also a concept; only man knows death. But culture triumphs over death and offers man eternal life. Thus, culture may deny satisfactions on the one hand while it fulfills desires on the other.

The predominant emphasis, perhaps, in studies of culture and personality has been the inquiry into the process by which the individual personality is formed as it develops under the influence of its cultural milieu. But the individual biologic organism is itself a significant determinant in the development of personality. The mature personality is, therefore, a function of both biologic and cultural factors, and it is virtually impossible to distinguish these factors from each other and to evaluate the magnitude of each in particular cases. If the cultural factor were a constant, personality would vary with the variations of the neurosensory-glandular-muscular structure of the individual. But there are no tests that can indicate, for example, precisely how much of the taxicab driver's ability to make change is due to innate endowment and how much to cultural experience. Therefore, the student of culture and personality is driven to work with "modal personalities," that is, the personality of the typical Crow Indian or the typical Frenchman insofar as this can be determined. But it is of interest, theoretically at least, to note that even if both factors, the biologic and the cultural, were constant—which they never are in actuality—variations of personality would still be possible. Within the confines of these two constants, individuals might undergo a number of profound experiences in different chronological permutations. For example, two young women might have the same experiences of (1) having a baby, (2) graduating from college, and (3) getting married. But the effect of sequence (1), (2), (3) upon personality development would be quite different than that of sequence (2), (3), (1).

CULTURAL COMPARISONS

Ethnocentrism. Ethnocentrism is the name given to a tendency to interpret or evaluate other cultures in terms of one's own. This tendency has been, perhaps, more prevalent in modern nations than among preliterate tribes.

The citizens of a large nation, especially in the past, have been less likely to observe people in another nation or culture than have been members of small tribes who are well acquainted with the ways of their culturally diverse neighbours. Thus, the American tourist could report that Londoners drive "on the wrong side of the street" or an Englishman might find some customs on the Continent "queer" or "boorish," merely because they are different. Members of a Pueblo tribe in the American Southwest, on the other hand, might be well acquainted with cultural differences not only among other Pueblos but also in non-Pueblo tribes such as the Navajo and Apache.

Ethnocentrism became prominent among many Europeans after the discovery of the Americas, the islands of the Pacific, and the Far East. Even anthropologists might characterize all preliterate peoples as being without religion (as did Sir John Lubbock) or as having a "prelogical mentality" (as did Lucien Lévy-Bruhl) merely because their ways of thinking did not correspond with those of the culture of western Europe. Thus, inhabitants of non-Western cultures, particularly those lacking the art of writing, were widely described as being immoral, illogical, queer, or just perverse ("Ye Beastly Devices of ye Heathen").

Cultural relativism. Increased knowledge led to or facilitated a deeper understanding and, with it, a finer appreciation of cultures quite different from one's own. When it was understood that universal needs could be served with culturally diverse means, that worship might assume a variety of forms, that morality consists in conforming to ethical rules of conduct but does not inhere in the rules themselves, a new view emerged that each culture should be understood and appreciated in terms of itself. What is moral in one culture might be immoral or ethically neutral in another. For example, it was not immoral to kill a baby girl at birth or an aged grandparent who was nonproductive when it was impossible to obtain enough food for all; or wife lending among the Eskimo might be practiced as a gesture of hospitality, a way of cementing a friendship and promoting mutual aid in a harsh and dangerous environment, and thus may acquire the status of a high moral value.

The view that elements of a culture are to be understood and judged in terms of their relationship to the culture as a whole—a doctrine known as cultural relativism—led to the conclusion that the cultures themselves could not be evaluated or graded as higher and lower, superior or inferior. If it was unwarranted to say that patriliny (descent through the male line) was superior or inferior to matriliny (descent through the female line), if it was unjustified or meaningless to say that monogamy was better or worse than polygamy, then it was equally unsound or meaningless to say that one culture was higher or superior to another. A large number of anthropologists subscribed to this view; they argued that such judgments were subjective and therefore unscientific.

The question of subjective judgments

It is, of course, true that some values are imponderable and some criteria are subjective. Are people in modern Western culture happier than the Aborigines of Australia? Is it better to be a child than an adult, alive than dead? These certainly are not questions for science. But to say that the culture of the ancient Mayas was not superior to or more highly developed than the crude and simple culture of the Tasmanians or to say that the culture of England in 1966 was not higher than England's culture in 1066 is to fly in the face of science as well as of common sense.

Evaluative grading. Cultures have ponderable values as well as imponderable, and the imponderable ones can be measured with objective, meaningful yardsticks. A culture is a means to an end: the security and continuity of life. Some kinds of culture are better means of making life secure than others. Agriculture is a better means of providing food than hunting and gathering. The productivity of human labour has been increased by machinery and by the utilization of the energy of nonhuman animals, water and wind power, and fossil fuels. Some cultures have more effective means of coping with disease than others, and this superiority is expressed mathematically in death rates. And there are many other ways in which meaningful differences can be measured and evaluations made. Thus, the proposition that cultures have ponderable values that can be measured meaningfully by objective yardsticks and arranged in a series of stages, higher and lower, is substantiated. But, it should be noted, this is not equivalent to saying that man is happier or that the dignity of the individual (an imponderable) is greater in an industrialized or agricultural sociocultural system than in one supported by human labour alone and sustained wholly by wild foods.

Actually, however, there is no necessary conflict between the doctrine of cultural relativism and the thesis that cultures can be objectively graded in a scientific manner. It is one thing to reject the statement that monogamy is better than polygamy and quite another to deny that one kind of sociocultural system contains a better means of providing food or combating disease than another.

CULTURAL ADAPTATION AND CHANGE

Ecological or environmental change. Every sociocultural system exists in a natural habitat, and, of course, this environment exerts an influence upon the cultural system. The cultures of some Eskimo groups present remarkable instances of adaptation to environmental conditions: tailored fur clothing, snow goggles, boats and harpoons for hunting sea mammals, and, in some instances, hemispherical snow houses, or igloos. Some sedentary, horticultural tribes of the upper Missouri River went out into the Great Plains and became nomadic hunters after the introduction of the horse. The culture of the Navajos underwent profound change after they acquired herds of sheep and a market for their rugs was developed. The older theories of simple environmentalism, some of which maintained that even styles of myths and tales were determined by topography, climate, flora, and other factors, are no longer in vogue. The present view is that the environment permits, at times encourages, and also prohibits the acquisition or use of certain cultural traits but otherwise does not determine culture change. The Fuegians living at the southern tip of South America, as viewed by Charles Darwin on his voyage on the *Beagle,* lived in a very cold, harsh environment but were virtually without both clothing and dwellings.

Diffusion. "Culture is contagious," as a prominent anthropologist once remarked, meaning that customs, beliefs, tools, techniques, folktales, ornaments, and so on may diffuse from one people or region to another. To be sure, a culture trait must offer some advantage, some utility or pleasure, to be sought and accepted by a people. (Some anthropologists have assumed that basic features of social structure, such as clan organization, may diffuse, but a sounder view holds that these features involving the organic structure of the society must be developed within societies themselves.) The degree of isolation of a sociocultural system—brought about by physical barriers such as deserts, mountain ranges, and bodies of water—has, of course, an important bearing upon the ease or difficulty of diffusion. Within the limits of desirability on the one hand and the possibility of communication on the other, diffusion of culture has taken place everywhere and in all times. Archaeological evidence shows that amber from the Baltic region diffused to the Mediterranean coast; and, conversely, early coins from the Middle East found their way to northern Europe. In aboriginal North America, copper objects from northern Michigan have been found in mounds in Georgia; macaw feathers from Central America turn up in archaeological sites in northern Arizona. Some Indian tribes in northwestern regions of the United States had possessed horses, originally brought into the Southwest by Spanish explorers, years before they had ever even seen white men. The wide dispersion of tobacco, corn (maize), coffee, the sweet potato, and many other traits are conspicuous examples of cultural diffusion.

Evidence of diffusion in the ancient past

Acculturation. Diffusion may take place between tribes or nations that are approximately equal in political and military power and of equivalent stages of cultural development, such as the spread of the sun dance among the Plains tribes of North America. But in other instances, it takes place between sociocultural systems differing widely in this respect. Conspicuous examples of this have been

instances of conquest and colonization of various regions by the nations of modern Europe. In these cases it is often said that the culture of the more highly developed nation is "imposed" upon the less developed peoples and cultures, and there is, of course, much truth in this; the acquisition of foreign culture by the subject people is called acculturation and is manifested by the indigenous populations of Latin America as well as of other regions. But even in cases of conquest, traits from the conquered peoples may diffuse to those of the more advanced cultures; examples might include, in addition to the cultivated plants cited above, individual words (*coyote*), musical themes, games, and art motifs.

One of the major problems of ethnology during the latter half of the 19th and the early decades of the 20th centuries was the question "How are cultural similarities in noncontiguous regions to be explained?" Did the concepts of pyramid building, mummification, and sun worship originate independently in ancient Egypt and in the Andean highlands and in Yucatán or did these traits originate in Egypt and diffuse from there to the Americas, as some anthropologists have believed? Some schools of ethnological theory have held to one view, some, to another. The 19th-century classical evolutionists (which included Edward Burnett Tylor and Lewis H. Morgan, among others) held that the mind of man is so constituted or endowed that he will develop cultures everywhere along the same lines. "Diffusionists"—those, such as Fritz Graebner and Elliot Smith, who offered grand theories about the diffusion of traits all over the world—maintained that man was inherently uninventive and that culture, once created, tended to spread everywhere. Each school tended to insist that its view was the correct one, and it would continue to hold that view unless definite proof of the contrary could be adduced.

The tendency nowadays is not to side categorically with one school as against another but to decide each case on its own merits. The consensus with regard to pyramids is that they were developed independently in Egypt and the Americas because they differ markedly in structure and function: the Egyptian pyramids were built of stone blocks and contained tombs within their interiors. The American pyramids were constructed of earth, then faced with stone, and they served as the bases of temples. The verdict with regard to the bow and arrow is that it was invented only once and subsequently diffused to all regions where it has been found. The probable antiquity of the origin of fire making, however, and the various ways of generating it—by percussion, friction, compression (fire pistons)—indicate multiple origins.

Evolution. Evolution of culture—that is, the development of forms through time—has taken place. No amount of diffusion of picture writing could of itself, for instance, produce the alphabetic system of writing; as Tylor demonstrated so well, the art of writing has developed through a series of stages, which began with picture writing, progressed to hieroglyphic writing, and culminated in alphabetic writing. In the realm of social organization there was a development from territorial groups composed of families to segmented societies (clans and larger groupings). Sociocultural evolution, like biologic evolution, exhibits a progressive differentiation of structure and specialization of function.

Relationship between diffusion and evolution

A misunderstanding has arisen with regard to the relationship between evolution and diffusion. It has been argued, for example, that the theory of cultural evolution was unsound because some peoples skipped a stage in a supposedly determined sequence; for example, some African tribes, as a consequence of diffusion, went from the Stone Age to the Iron Age without an intermediate age of copper and bronze. But the classical evolutionists did not maintain that peoples, or societies, had to pass through a fixed series of stages in the course of development, but that tools, techniques, institutions—in short, culture—had to pass through the stages. The sequence of stages of writing did not mean that a society could not acquire the alphabet without working its way through hieroglyphic writing; it was obvious that many peoples did skip directly to the alphabet.

Approaches to the study of culture

VIEWING CULTURE IN TERMS OF PATTERNS AND CONFIGURATIONS

Cultural traits. The concept of culture embraces the culture of mankind as a whole. An understanding of human culture is facilitated, however, by analyzing "the complex whole" into component parts or categories. In somewhat the same sense that the atom has been regarded as the unit of matter, the cell as the unit of life, so the culture trait is generally regarded as the unit of culture. A trait may be an object (knife), a way of doing something (weaving), a belief (in spirits), or an attitude (the so-called horror of incest). But, within the category of culture, each trait is related to other traits. A distinguishable and relatively self-contained cluster of traits is conventionally called a culture complex. The association of traits in a complex may be of a functional and mechanical nature, such as horse, saddle, bridle, quirt, and the like, or it may lie in conceptional or emotional associations, such as the acts and attitudes involved in seclusion in a menstrual hut or retrieving a heart that has been stolen by witches.

Cultural areas. The relationship between an actual culture and its habitat is always an intimate one, and therefore one finds a more or less close correlation between kind of habitat and type of culture. This results in the concept of culture area. This conception goes back at least as far as the early 19th century, but it was first brought into prominence by the U.S. anthropologist Clark Wissler in *The American Indian* (1917) and *Man and Culture* (1923). He divided the Indian cultures (as they were in the latter half of the 19th century) into geographic cultural regions: the Caribou area of northern Canada; the Northwest coast, characterized by the use of salmon and cedar; the Great Plains, where tribes hunted bison with the horse; the Pueblo area of the Southwest; and so on. Others later distinguished culture areas in other continents.

Cultural types. Appreciation of the relationship between culture and topographic area suggests the concept of culture type, such as hunting and gathering or a special way of hunting—for example, the use of the horse in bison hunting in the Plains or the method of hunting of sea mammals among the Eskimo; pastoral cultures centred upon sheep, cattle, reindeer, and so on; and horticulture (with digging stick and hoe) and agriculture (with ox-drawn plow). Less common are trading cultures such as are found in Melanesia or specialized production of some object for trade, such as pottery, bronze axes, or salt, as was the case in Luzon.

Culture configurations and patterns

Configuration and pattern, especially the latter, are concepts closely related to culture area and culture type. All of them have one thing in common; they view culture not in terms of its individual components, or traits, but as meaningful organizations of traits: areas, occupations, configurations (art, mathematics, physics), or patterns (in which psychological factors are the bases of organization). Clark Wissler's "universal culture pattern" was a recognition of the fact that all particular and actual cultures possess the same general categories: language, art, social organization, religion, technology, and so on.

VIEWING CULTURE IN TERMS OF INSTITUTIONAL STRUCTURE AND FUNCTIONS

Social organization. A sociocultural system presents itself under two aspects: structure and function. As culture evolves, sociocultural systems (like biologic systems) become more differentiated structurally and more specialized functionally, proceeding from the simple to the complex. Systems on the lowest stage of development have only two significant kinds of parts: the local territorial group and the family. There is a corresponding minimum of specialization, limited, with but few exceptions, to division of function, or labour, along sex lines and to division between children and adults. The exceptions are headmen and shamans; they are special organs, so to speak, in the body politic. The headman is a mechanism of social integration, direction, and control, expressing, however, the consensus of the band. The shaman, though a self-appointed priest or magician, is also an instrument of

society; he may be regarded as the first specialist in the history of human society.

Classes and segments

All human societies are divided into classes and segments. Class is defined as one of an indefinite number of groupings each of which differs in composition from the other or others, such as men and women; married, widowed, and divorced; children and adults. Segment is defined as one of an indefinite number of groupings all of which are alike in structure and function: families, lineages, clans, and so on. On more advanced levels of development there are occupational classes, such as farmers, pastoralists, artisans, metalworkers, and scribes, and territorial segments, such as wards, barrios, counties, and states.

Segmentation is a cultural process essential to the evolution of culture; it is a means of increasing the size of a society or a grouping within a sociocultural system (such as an army) and therefore of increasing its power to make life secure, without suffering a corresponding loss of effectiveness through diminished solidarity; segmentation is a means of maintaining solidarity at the same time that it enlarges the social grouping. A tribe could not increase in size beyond a certain point without resorting to segmentation: the formation of lineages, clans, and the like. The word clannish points to one of the functions of segments in general: the fostering of solidarity. Tribes become segments in confederacies; and above the tribal level, the evolution of civil society employs barrios, demes, counties, and states in its process of segmentation. In present-day society, the army and the church offer illuminating examples of increased size and sustained solidarity proceeding hand in hand.

Economic systems. Division of labour along occupational lines is rare, although not wholly lacking, in preliterate societies—despite a widespread notion that one member of a tribe specializes in making arrows, which he exchanges for moccasins made by another specialist. Occupational groupings were virtually lacking in all cultural systems of aboriginal North America, for example. Guilds of metalworkers are found in some African tribes and specialists in canoe making and tattooing existed in Polynesia. But it is not until the transition from preliterate society, based upon ties of kinship, to civil society, based upon property relations and territorial distinctions (the state), that division of labour along occupational lines becomes extensive. On this level there are found many kinds of specialists: metalworkers, scribes, astrologers, soldiers, dancers, musicians, alchemists, prostitutes, eunuchs, and so forth.

Distribution and exchange of goods

Production of goods is everywhere followed by distribution and exchange. Among the Kurnai of Australia, for example, game was divided and distributed as follows: the hunter who killed a wallaby, for example, kept the head; his father received the ribs on the right side, his mother the ribs on the left side, plus the backbone, and so on; the various parts of the animal went to various classes of relatives in accordance with fixed, traditional rules.

Distribution along kinship lines constitutes a system of circulation and exchange within the tribe as a whole, for everyone is a relative of everyone else. It takes the form of bestowing gifts to relatives on all sorts of occasions—such as birth, initiation, marriage, death. In some cases there is an exchange of goods on the spot, but more often A gives something to B who gives A a gift at a later date. All this takes place in the network of rights and obligations among kindred; one has both an obligation to give and a right to receive on certain occasions and in certain contexts. The whole process is one of mutual aid and cooperation.

The consequence of this form of distribution and exchange is that the recipient receives kinds of things that he already has; each household has the same kinds of foods, utensils, ornaments, and other things that every other household has. Why, then, it might be asked, does this form of exchange take place? Two reasons may be distinguished. First, this kind of exchange fortifies ties of kinship and mutual aid—as neighbourhood exchange among households in modern American culture initiates friendships that in times of need constitute mutual aid. Second, this system of circulation of goods is in effect a system of social security: a household in need, due to illness or accident, receives help from the community ("No household can starve as long as others have corn," as the Iroquois put it). Here we have an economic system subordinated to the welfare of the society as a whole.

Exchange or circulation of goods and services (a basket is the material form of "a service," that is, human labour) must, of course, take place in sociocultural systems where division of labour finds expression in specialization: the ironworker must obtain food; the horticulturalist needs an iron hoe.

Exchange of goods between sociocultural systems is universal and takes place on the lowest levels of cultural development. In some instances it is the only form of nonhostile communication: in the so-called silent trade the actual exchange takes place in a neutral zone without the presence of the participating parties. Archaeological evidence shows that intergroup exchange occurred in remote times and over great distances, as already noted above in the discussion of diffusion.

An interesting form of the circulation of goods—usually referred to as redistribution—occurs among more highly developed tribes. The head of the sociopolitical system, that is, the chief or priest-chief, imposes levies upon all households, thus acquiring a large amount of goods—food, utensils, art objects, and so on—which he then redistributes to the households of the tribe. This may take the form and occasion of ceremonies and feasts or distribution may be made in cases of need. This widespread and interesting form of redistribution serves the same ends as those served by distribution as a function of the kinship system, namely, fostering solidarity and social security—an equitable distribution that tends to iron out inequalities among households.

Ownership and use

Some economic concepts in modern Western culture do not correspond closely with conceptions and customs in many preliterate societies. Ownership is a case in point. Complete possession of and exclusive right to use something in an economic context, such as land, a dwelling, or a boat, is rare, if not wholly lacking, in preliterate societies (although one might have exclusive rights to a dream, spell, or charm). In general, one has merely the right to use or occupy a tract of land or a house; when its use has terminated, anyone can take it over. In some societies it might be said that a boat "belonged" to the men who made it or even to the individual who initiated its construction. But anyone else in the community would have the right to use it when the "owners" (the men who made it) were not using it. It is the right to use, rather than exclusive and absolute possession, that is significant; there is no such thing as absentee ownership in primitive society.

A band or tribe "holds" the land it occupies; here again, it is tenure rather than ownership that is significant; the land "belongs" to Nature, or Mother Earth; people merely hold and use it. There is usually an intimate relationship between the people and "their" land. Navajo Indians fell on their knees and kissed the earth when they were returned to their former territory after forcible detention in an alien land. Land is defended against outsiders, except when they are accepted as guests, but the significant thing is not that the outsiders do not own the land but that they pose a threat to those who occupy it.

In some tribes there is a distinct conception that the land held "belongs" to the tribe, the chief of which allots plots or tracts to individuals or households for their use. But when use terminates, the land reverts to the tribal domain.

During the latter part of the 19th century there was considerable discussion of "primitive communism." This doctrine came to be interpreted as meaning that private property, the private right to hold or use, was nonexistent in primitive society. It was extended also to communism in wives and children in some tribes; this was interpreted to be a vestige of a former stage of "primordial promiscuity." Many ethnologists, however, launched a vigorous attack upon "the doctrine of primitive communism." Some of the conceptions of earlier anthropologists—such as group marriage—were shown to be unwarranted in the light of later research.

Today, with these polemics well in the past, the situa-

tion with regard to property rights in tribal societies may be summarized as follows. Tenure and use, rather than ownership in fee simple, were the significant concepts and practices. Private, or personal, possession of goods and use of land were recognized. But possession and right were qualified by the rights and obligations of kinship: one had an obligation both to give and to receive within the body of kindred, according to specific rules. In a de facto sense, things belonged to the body of kindred; rights of possession and use were regulated by customs of kinship. In some cultures a borrower was not obliged to return an object borrowed, on the theory that if a person could afford to lend something, he relinquished his right to its possession. The mode of life in preliterate society, based upon kinship and functioning in accordance with the principles of cooperation and mutual aid, did indeed justify the adjective communal; it was the noun communism that was resented—if not feared—because of its Marxist connotation.

One of the most important, as well as characteristic, features of the economic life of preliterate societies, as contrasted with modern civilizations, is this: no individual and no class or group in tribal society was denied access to the resources of nature; all were free to exploit them. This is, of course, in sharp contrast to civil society in which private ownership by some, or a class, is the means of excluding others—slaves, serfs, a proletariat—from the exploitation and enjoyment of the resources of nature. It is this freedom of access, the freedom to exploit and to enjoy the resources of nature, that has given primitive society its characteristics of freedom and equality. And, being based upon kinship ties, it had fraternity as well (see also ECONOMIC SYSTEMS).

Socialization or enculturation

Education. In the human species individuals are equipped with fewer instincts than is the case in many nonhuman species. And, as already noted, they are born cultureless. Therefore an infant *Homo sapiens* must learn a very great deal and acquire a vast number of conditioned reflexes and habit patterns in order to live effectively, not only in society but in a particular kind of sociocultural system, be it Tibetan, Eskimo, or French. This process, taken as a whole, is called socialization (occasionally, enculturation)—the making of a social being out of one that was at birth wholly individualistic and egoistic.

Education in its broadest sense may properly be regarded as the process by which the culture of a sociocultural system is impressed or imposed upon the plastic, receptive infant. It is this process that makes continuity of culture possible. Education, formal and informal, is the specific means of socialization. By informal education is meant the way a child learns to adapt his behaviour to that of others, to be like others, to become a member of a group. By formal education is meant the intentional and more or less systematic effort to affect the behaviour of others by transmitting elements of culture to them, be it knowledge or belief, patterns of behaviour, or ideals and values. These attempts may be overt or covert. The teacher may make his purpose apparent, even emphatic, to the learner. But much education is effected in an unobtrusive way, without teacher or learner being aware that culture is being transmitted. Thus, in myths and tales, certain characters are presented as heroes or villains; certain traits are extolled, others are deplored or denounced. The impressionable child acquires ideals and values, an image of the good or the bad.

The growing child is immersed in the fountain of informal education constantly; the formal education tends to be periodic. Many sociocultural systems distinguish rather sharply a series of stages in the education and development of full-fledged men and women. First there is infancy, during which perhaps the most profound and enduring influences of a person's life are brought to bear. Weaning ushers in a new stage, that of childhood, during which boys and girls become distinguished from each other. Puberty rites transform children into men and women. These rites vary enormously in emphasis and content. Sometimes they include whipping, isolation, scarification, or circumcision. Very often the ritual is accompanied by explicit instruction in the mythology and lore of the tribe and in ethical codes. Such rituals as confirmation and Bar Mitzvah in modern Western culture belong to the category of puberty rites.

With marriage come instruction and admonition, appropriate to the occasion, from elder relatives and, in more advanced cultures, from priests. In some sociocultural systems men may become members of associations or sodalities: men's clubs, warrior societies, secret societies of magic or medicine. In some cases it is said that in passing through initiation rites a person is "born again." Women also may belong to sodalities, and in some instances they may become members of secret, magical societies along with men.

Religion and belief. Man's oldest philosophy is animism, the doctrine that everything is alive and possesses mental faculties like those possessed by man: desire, will, purpose, anger, love, and the like. This philosophy results from man's projection of his own self, his psyche, into other things and beings, inanimate and living, without being aware of this projection. "To the Omaha," wrote anthropologist Alice Fletcher,

> nothing is without life: . . . He projects his own consciousness upon all things and ascribes to them experiences and characteristics with which he is familiar; . . . akin to his own conscious being.
>
> ("Wakonda," in F.W. Hodge [ed.], *Handbook of American Indians North of Mexico*)

Development of religion

"A belief in spirits is," according to Edward Burnett Tylor, "the minimum definition of religion." Some later students, however, made the same claim for a belief in impersonal, supernatural power, or mana (manitou, orenda, and so on). In any case, these two elements of religion are virtually worldwide and undoubtedly represent a very early stage in the development of religion. In some cultures spirits are virtually innumerable, but, in the course of time, the more important spirits become gods. Thus, there has been a tendency toward monotheism in the history of religion. The German Roman Catholic priest and anthropologist Father Wilhelm Schmidt argued not only that some primitive peoples believe in a Supreme Being but that monotheism was characteristic of the earliest and simplest cultures. Schmidt's thesis, however, has been severely criticized by other ethnologists. Also, as Tylor pointed out many years ago, the Supreme Being of some very primitive peoples is an originator god, or a philosophical explanatory device, accountable only for the existence and structure of the world; after his work was completed, he had no further significance; he was not worshiped and played no part in the daily lives of the people.

Magic and religion

In the past there was much discussion—and debate—about the difference between magic and religion. Both were deemed expressions of a belief in the supernatural. Some argued that religion was social (moral) whereas magic was antisocial (immoral). Another distinction was that magic was the use of supernatural power divorced from a spiritual being. The distinction between religion and magic was so beset with exceptions as to render most definitions of these terms logically imperfect. Another difficulty was the tacit assumption that different entities, religion and magic, exist per se, and therefore that "correct" definitions of them must exist also (Adam called the animal a horse because it was a horse). Much confusion and debate would have been obviated if it had been recognized (as it generally is now) that there is no such thing as a "correct" definition—all definitions are man-made and arbitrary—and that the problem is not what religion or magic are but what beliefs, events, and experiences one wishes to designate with the words religion and magic (see also OCCULTISM: *Magic;* RELIGIONS, THE STUDY AND CLASSIFICATION OF).

Custom and law. Sociocultural systems, like other kinds of systems, must have means of self-regulation and control in order to persist and function. In human society these means are numerous and varied. The kinship organization specifies reciprocal and correlative rights, duties, and obligations of one class of relatives to another. Codes of ethics govern the relationship of the individual to the well-being of society as a whole. Codes of etiquette regulate class structure by requiring individuals to conform

to their respective classes. Custom is a general term that embraces all these mechanisms of regulation and control and even more. Custom is the name given to uniformities in sociocultural systems. Uniformities are important because they make anticipation and prediction possible; without them, orderly conduct of social life would not be possible. Custom, therefore, is a means of social regulation and control, of effecting compliance with itself in order to render effective conduct of social life possible.

As in the case of religion and magic, much effort and debate have been spent in attempts to achieve a clean-cut distinction between custom and law. There is little or no difficulty when one is concerned with the extremes of the spectrum of social control. The way that a Hopi Indian holds his corn-husk cigarette in his hand is a matter of custom rather than law, as most ethnologists would probably agree. At the other extreme, a state edict prohibiting the manufacture and sale of alcoholic beverages is a law, not a custom. But in other situations the distinction is far from clear, and disagreement with regard to definitions arises. For example, in marriage the obligation to wed someone within a specified group or class (endogamy) or outside a group or class (exogamy) has been called both law and custom. Probably the most useful distinction between custom and law is the following. If an infraction of a social rule or deviation from a norm is punished merely by expressions of social disapproval, gossip, ridicule, or ostracism, the rule is called custom. If, however, infractions or violations are punished by an agency, designated by society and empowered to act on its behalf, then the rule is called a law. But even here there is difficulty. The same kind of offense may be punished by custom in one society, by law in another—as in, for example, adultery, incest, miscegenation, and black magic.

It is the ethnologist, rather than the historian, who is disturbed by instances of ambiguity with regard to custom and law; in preliterate societies the distinction between the two is not always clear. But in civil societies—that is, states brought into being by the agricultural revolution and their more recent successors—the distinction is usually sharper and more apparent, though instances of sumptuary laws that prohibit the wearing of silk or that limit the length of a garment merge law and custom or reinforce the latter by the former.

One need not be unduly disturbed by the difficulty of making sharp distinctions among sociocultural phenomena and of formulating definitions. The phenomena of culture, like those of the external world in general, are what they are, and if man-made concepts and words do not correspond closely with them, one may regret the lack of fit. But it is better to do this than to distort real phenomena by trying to force them into artificial concepts and definitions. (L.A.W.)

Nonurban cultures

So great are the variations in ways of life, past and present, that comparisons among them are difficult. Any simple classification of human societies and cultures can only be viewed as arbitrary. From a modern urban point of view, nevertheless, there is the obvious distinction between the primitive and the civilized: between simple and complex societies; between tiny and huge social agglomerations; between scattered and dense populations; and, above all, between prestate societies and societies that have developed states. In general, civilization involves the rise of legal institutions and the acquisition of a legal monopoly of force by a government. Those developments made possible the cities and empires of classical times and the growth of dense populations. Thus "civilized" is nearly synonymous with "urban."

Primitive and civilized

The varieties of nonurban, or primitive, societies may be further classified. One way is by the methods they use to get food. Those who hunt and gather behave quite differently, as societies, from herdsmen and mounted predator-warriors, the pastoralists, who in turn live quite differently from the various kinds of agriculturalists. These distinctions are not sharp, for of course there are societies that combine foraging with some agriculture, others, some agriculture and some herding; and, in a few cases, a class of herders may live in the same society with a class or caste of agriculturalists. A continuum of societies may be constructed, ranging from tiny, simple bands of hunter-gatherers in poor environments to large, dense populations of irrigation agriculturalists—that is, from the entirely nomadic to the fully sedentary. The degree to which societies approach the sedentary deserves prominence in any classification since sedentary ways are accompanied by many other cultural traits and institutions.

NOMADIC SOCIETIES

Throughout 99 percent of the time that *Homo sapiens* has been on Earth, or until about 8,000 years ago, all peoples were foragers of wild food. There were great differences among them; some specialized in hunting big game, fishing, and shellfish gathering, while others were almost completely dependent on the gathering of wild plants. Broadly speaking, however, they probably shared many features of social and political organization, as well as of religions and other ideologies (in form though not in specific content). The hunting-gathering societies declined with the growth of agricultural societies, which either drove them from their territories or assimilated or converted them.

The later rise of the nation-states, especially after the Industrial Revolution in Europe, resulted in the near extermination of hunting-gathering societies. Today, the remaining ones are confined to desert, mountain, jungle, or Arctic wastelands. Some have been studied and described by anthropologists: the central and northern Australians, the Bushmen of the Kalahari in southern Africa, the Pygmies of the central African forests, the Pygmies of the Andaman Islands in the Indian Ocean, the Ona and Yahgan Indians of southern South America, the "Digger" Indians of Nevada, the Indians of the northern Canadian forests, and the Canadian, Alaskan, and Greenland Eskimos.

All of these peoples inhabit areas representing almost every extreme in climate and environment, but they have one thing in common: their marginality to, or relative isolation from, modern economic systems. Their techniques and forms of acquiring food vary greatly. The Eskimos, for example, are entirely dependent on hunting and fishing; the African San (Bushmen), the Australian Aborigines, and the Nevada Indians are chiefly dependent on the gathering of seeds, nuts, and tubers.

The significance of nomadism to the student of primitive cultures may be suggested by a comparison of the Ona and Yámana (Yahgan) of Tierra del Fuego. The Ona inhabit the interior forests and depend heavily on hunting guanaco (a small New World camel). The Yámana are canoe-using fishermen and shellfish gatherers. Yet, despite their utterly different ecological adaptation, the two Indian societies have cultures that are so similar that anthropologists conventionally group them with the neighbouring Chono and Alakaluf of Chile into one "Fuegian culture area." They are all nomadic, though the Ona are "foot Indians" and the others are "canoe Indians"; they are all relatively sparsely scattered over the landscape and poor in material culture, and they have similar social, political, ceremonial, and ideological customs and institutions.

Common characteristics of nomadic societies

All of the nomads so far mentioned share important general characteristics. The first and most obvious is that their nomadism severely restricts the amount of their "baggage," or material culture. Bows and arrows (except in Australia, where the unique boomerang is used instead) and perhaps a simple spear javelin, or in some areas throwing sticks or clubs, are the usual hunting and fighting weapons. In warmer zones shelter is a simple lean-to or small beehive hut of sticks, twigs, and leaves. In Arctic zones there are the caribou-skin tent and the famous Eskimo igloo—or, in more permanent or revisited places, the stone hut.

Camps are small and impermanent. The nuclear family likes to camp near related families when possible. Usually this group forms the patrilineally extended family consisting of brothers with their own nuclear families and perhaps a few dependent elders. But the size of the camp depends on the season: in times of easily gathered plant food, large groups may come together for ceremonies such as puberty rites. At other times, the constituent families may scatter

widely because food and water are scarce. Patrilineally related men and their families, scattered or not, commonly regard themselves as a group with rights over a particular territory and may be distinguished from neighbours on a territorial basis as well. Marriages are often arranged among territorial groups so that contiguous groups tend to be related, or at least certain members of different groups are related. But this is the only organizing principle that extends beyond the territorial band. Each band may be thought of as part of a larger society composed of distant as well as close relatives—a "tribe" in one of the original meanings of the word.

The social organization looks as though it had been built up from within, so to speak. Family-like statuses and roles, alliances by marriage, and systems of "social distance" based on family relationships are the bones and connective tissues of the society. These are all ingredients of the family itself, however extended or metaphorically construed; it is as though these societies were simply the result of the growth of individual families. But this is only appearance; such societies also grow by accretion. But inasmuch as alliances and the compounding of different groups normally are brought about by arranged marriages, the familistic appearance of the whole is therefore maintained.

The shaman

Almost all status positions rest upon the same criteria of age, sex, and kinship distance. The only achieved status is that of the magical curer, the shaman. Again, with the exception of the shaman, the only division of labour in these societies is on the basis of age and sex—just as in the individual nuclear family unit. Among adults, the hunting of big game is confined to men, whereas the gathering of vegetable foods or small animals, birds' eggs, and so on are women's tasks. This division of labour seems obviously related to men's relative ability to range far from camp, women being too burdened with the tasks of motherhood to track animals wherever they may lead. But the separation of tasks is usually more rigid and confining than the physical and circumstantial differences between men and women dictate, since these would vary among individuals and from society to society—and for that matter, from day to day. Domestic tasks are strictly defined as female and are undertaken only by women even when they seem exceptionally taxing, as attest the following remarks by Lewis Garrard, who traveled with a Cheyenne Indian camp in 1846:

> After a ride of two hours, we stopped, and the chiefs, fastening their horses, collected in circles, to smoke the pipe and talk, letting their squaws unpack the animals, pitch the lodges, build fires, arrange the robes, and when all was ready, these "lords of creation" dispersed to their several homes, to wait until their patient and enduring spouses prepared some food. I was provoked, nay, angry, to see the lazy, overgrown men, do nothing to help their wives; and, when the young women pulled off their bracelets and finery, to chop wood, the cup of my wrath was full to overflowing, and, in a fit of honest indignation, I pronounced them ungallant, and indeed savage in the true sense of the word.
>
> (*Wah-To-Yah and the Taos Trail;* University of Oklahoma Press, Norman, Okla., 1966)

Status within the family is based on age, sex, relationships by blood, or marriageability. Males are regarded as superior to women in most activities; the elders are respected as repositories of both secular and spiritual wisdom; and people, such as cousins who may be of the same genealogical distance, are frequently divided into "marriageable" and "nonmarriageable" groups, with consequent differences in their interpersonal behaviour. But in all other respects hunting-gathering societies are profoundly egalitarian, especially in intergroup relations.

Outside the family there is no system of coercive authority. Some persons may, by their wisdom, physical ability, and so on, rise to positions of leadership in some particular endeavour, such as a raiding party or a hunt. But these are temporary and variable positions, not posts or offices within a hierarchical structure. Social order is maintained by emphasizing correctness in conduct—etiquette—and ritual and ceremony. Ceremonies bring together the scattered members of the society to celebrate birth, puberty, marriage, and death. Such ceremonies have the effect of minimizing social dangers (or the perception of them) and also of adjusting persons to each other under controlled emotional conditions. (It may very well be true that "the family that prays together, stays together.")

The passage rites at birth, marriage, and death are universal in human society, though puberty celebrations are less common in the modern world, except for such survivals as the Jewish Bar Mitzvah. In most hunting-gathering societies, however, male puberty rituals take up more social time and engage more people than do the other three ritual occasions. They may last as long as a month, food supplies permitting. Almost universally, puberty rites include a period of instruction in adult responsibilities, rituals dramatizing the removal of boys from the mothers' care and signalizing the changed social relations between boys and girls of the same generation, and physical ordeals, including scarification or some other mark that will permanently demonstrate the successful passage to manhood.

The Plains Indians

The mounted buffalo hunters of the North American Great Plains, common in popular literature and cowboy movies, constituted a type of nomadic hunting society. But they represented a brief and very special development: an interaction and amalgamation of elements of Indian culture with Spanish horses and the training of them, as well as with metal and guns. The Indians, once mounted, could follow, surround, and kill tremendous numbers of buffalo, where previously the Indians had found the buffalo herds nearly impregnable. So productive was mounted buffalo hunting that tribes of diverse languages and customs were quickly drawn into the Great Plains from all directions. A distinctive, picturesque culture arose among them, reaching its peak about 1800. But from 1850 through the 1870s the tide of white settlers virtually wiped out the buffalo. By that time most of the Indians had been defeated in battle and confined to reservations.

Equestrian Indians can be regarded as a special form of nomadic hunters rather than as a form of pastoralists. Pastoral culture is dominated by the requirements of domesticated livestock and by the relation of herds to pasture. The Plains Indians' nomadism, however, was determined by the habits of the wild buffalo herds. The natural cycle of the buffalo was to concentrate in huge herds in summer and disperse into smaller groups in winter and spring. The Indians accordingly traveled in small camps of a few related families in winter and formed huge encampments in summer and fall for tribal ceremonies and organized cooperative hunts. The summer camps sometimes numbered several thousand people.

The continual intrusion of new groups into the Plains—first Indians, then whites—and the introduction of new weapons constantly altered the balance of power and kept the region in a state of belligerent turmoil. Equestrian bow-and-arrow Indians were superior militarily to those on foot; Indians with guns, of course, were superior to bow-and-arrow Indians; but Indians with both guns and horses—as happened in the Central Plains first—were vastly superior to the others. But the supply of horses and guns and especially ammunition continued to fluctuate wildly as access to sources varied greatly from place to place and time to time.

Nomadism places limitations on property and material technology, and the Plains Indians consequently manufactured no pottery, cloth, or basketry, although leatherwork and beadwork were highly developed. On the other hand, being equestrian, they could carry far more goods than nomadic hunters on foot. Perhaps the most notable thing they carried was the large conical tent (tepee) of decorated buffalo hide.

Sociopolitical organization was informal, probably because of the fluidity of the population. On the other hand, some tribal cohesion and systems of alliance were required because of the constant raiding. Consequently, a large number of pan-tribal associations arose, especially military societies and male age-graded societies.

Religion among the Plains Indians reflected the varying sources of the original religions of the pre-horse tribes. Some elements, however, became widespread in the Plains. The folk hero of a great many myths was the trickster Old Man Coyote. There was a widespread concept of Manitou, the pervasive spirit. Most notable was the nearly universal

importance attached to the Sun—but without the notion of the Sun as a supreme deity. Ordeals and self-torture and mass ritual self-torture were common Plains religious practices. The Indian tortured himself and fasted in order to suffer hallucinations that would reveal a personal guardian spirit for his protection in the hunt and in battle.

As in other nomadic hunting-gathering societies, principal ceremonies were related to the life cycle, with special prominence given to male puberty rites to instill bravery, endurance, and hunting and raiding skills.

SETTLED HUNTING AND GATHERING SOCIETIES

Outstanding examples of the settled hunters and gatherers were the peoples of the North Pacific Coast of North America, roughly from Oregon to southern Alaska. The resources of the sea and inlets and rivers were of astonishing variety, and some, like the salmon during their runs, were so easy to catch that the word "harvesting" seems more appropriate than "fishing" for this activity. In central and northern California there were numerous sedentary Indian groups, such as the Pomo, Wintun, and Yurok. Their basic food was the acorn, which was ground and stored as flour. Many of the streams had salmon, and the Indians also gathered roots and berries and hunted wild fowl and deer. Other sedentary hunter-gatherer societies are rare and scattered. The most prominent of these are in southwestern New Guinea, as represented by the Asmat. These groups rely on the sago palm, whose starchy pith is easily reduced to flour. Fish, wild birds, and semidomesticated pigs supplement the basic sago.

The effect of food on population and culture

The basic foods of these sedentary peoples had two common characteristics: they were reliable and they could be stored, much as can the products of agriculture. Salmon were smoke-dried and stored in wooden boxes by the Northwest Coast Indians, and acorn flour obviously could be stored just as can grain flour. Sago flour can also be stored, but it has no season; a palm can be cut at any time the food is required. So abundant and reliable are these resources that such peoples are said to practice a "natural agriculture."

Sedentary life makes possible many improvements in material culture. Houses become larger and more elaborate and are improved over time. The Asmat of New Guinea and the Northwest Coast Indians make huge houses of planks and are among the best wood-carvers of the primitive world.

Permanent villages and a consistent abundance of food make possible high population densities. The California tribes are estimated to have reached 11 or 12 persons per square mile, as did those of the Northwest Coast. The Asmat of New Guinea have villages ranging up to 2,000 people, which is from 10 to 20 times the size of the average hunting-gathering settlement. Usually such large villages remain politically independent. Intermarriages occur, of course, and some local cohesion is achieved by secret societies and other clublike associations. But such integration is only incidental.

The Northwest Coast Indians

The Northwest Coast Indians elaborated a hierarchical form of organization, or chiefdom. They were the only hunter-gatherers to have done so. Chiefs or nobles occupied positions of high status that were inherited in a single descent line by primogeniture. Secondary lines of descent, collateral to the above, were of lesser status. Finally, there were the commoners.

Along with chiefly status went the socioeconomic institution of redistribution. Surplus products of family production were passed on to the chief, who in turn gave a large feast (or "potlatch"), during which he distributed gifts to those who needed them. This process of redistribution had the economic function of encouraging specialization and division of labour. The potlatch in late times on the Northwest Coast became famous for its competitiveness. A chief of a lineage or longhouse, for example, would amass as much food and material goods as he could in order to lay on a feast and give presents lavishly in hopes that the guest lineage would be unable to reciprocate on the same scale. One lineage, house, or perhaps village thus might "defeat" the others.

The Northwest Coast Indian type of chiefdom is primarily social and economic. It can be called political only to the extent that a certain amount of personal authority for decision making may reside in a high social status. This authority can serve a purpose, however. The egalitarian nature of hunting-gathering bands tends toward anarchy, which becomes perilous in populous societies. Quarrels can turn into feuds for lack of a higher authority to settle them.

HORTICULTURAL SOCIETIES

Primitive agriculture is called horticulture by anthropologists rather than farming because it is carried on like simple gardening, supplementary to hunting and gathering. It differs from farming also in its relatively more primitive technology. It is typically practiced in forests, where the loose soil is easily broken up with a simple stick, rather than on grassy plains with heavy sod. Nor do horticulturalists use fertilizer intensively or crop rotation, terracing, or irrigation. Horticulture is therefore much less productive than agriculture. The villages are small—some no larger than many hunting-gathering settlements—and the overall population density is low compared with farming regions.

Forest horticulture

Forest horticulturists use fallowing techniques variously called "slash-and-burn," "shifting cultivation," and "swidden cultivation" (a northern English term now widely used by anthropologists). After about two years of cropping a plot is left fallow for some years and allowed to revert to secondary forest or bush. Before resuming cultivation the bush may be cut, left to dry, and then burned. The ashes bestow some fertilization, but the foremost benefit of this procedure is that the plot will be relatively weed free at first.

Since the fallowing periods of the plots are much longer than the planted periods, the swidden horticulturalists must gradually encroach on more distant land. Sometimes this results in semisedentary villages when the newly arable plots finally are so distant that a few horticulturalists must start to build huts near the newer fields, to be joined later by others. Such a land-hungry system, in a region of competing populations, greatly increases the chances of conflict. Population dispersal thus becomes a grave threat in horticultural regions. Land for expansion inevitably must be found at the expense of neighbours or by shortening the fallowing periods—which eventually results in lower production.

Many forest tribes—typical are the horticulturalists of the South American tropical forest—constantly maintain a military posture. Large-scale warfare is not usual (because of the lack of political leadership) but raids, cannibalism, torturing of captives, and other forms of belligerence are.

Horticulturalists have more material goods than most hunter-gatherers, though not more than such societies as the Indians of the Northwest Coast. This suggests that the accumulation of domestic goods is related not so much to the higher productivity of the horticulturalists as to their greater stability of settlement.

The most highly developed of aboriginal slash-and-burn horticulturalists were undoubtedly the Maya of Guatemala and Yucatán, who had a chiefdom or primitive state. But this was most exceptional, for almost all other primitive horticulturalists did not go beyond simple tribes with egalitarian and nearly autonomous communities. Any regional confederation was likely to be only on the basis of intermarriage and clanship. Sometimes an ephemeral sort of near-chiefdom arises, founded on the capabilities of a charismatic leader. In Melanesia, where a well-established form of personal politics thrives, the leader is called Big Man or Centre Man.

The Big Man of Melanesia

The Big Man in Melanesia is big because he has a following. He begins with his own family and near relatives and friends, who provide goods that he, on behalf of his group, gives away to other groups at a feast on some ceremonial occasion. He and his faction are feasted reciprocally by others at other times. His ability to redistribute on an increasingly lavish scale to larger groups expands his following. He thus amasses what the anthropologist Bronisław Malinowski, in reporting on the Trobriand Islanders, called a "fund of power." With the public esteem gained in this economic contest, the Big Man is sought

out for giving advice, adjudicating quarrels, planning ceremonies, and admonishing and conciliating. But this is influence, not the true authority that inheres in a status or office in an established hierarchy. A really big Big Man may succeed in integrating a region of several villages, but when he loses to a rival or dies, the unity of the region dissolves until some other unusually influential man unites it again.

In many respects the religion of horticultural peoples resembles that of hunting-gathering peoples. Shamans, life-crisis ceremonies—especially puberty rites—totemism (ceremonies for plant or animal species believed to be ancestral to particular human groups like clans or lineages), and the worship of animistic spirits are common in the religion of many kinds of primitive societies. The egalitarian society does not usually practice ancestor worship as does the hierarchical society. Among horticultural peoples with chiefdoms, the chief's ancestors, in time, become gods. The most remote ancestors, the founders of the chiefly lineage, are the most important gods; more recent ancestors and those of related but collateral lines have a lesser status. The result is a hierarchy of gods resembling the political hierarchy on Earth. Furthermore, the chiefdoms tend to be theocracies, with the hierarchy of priests closely and functionally related to the political hierarchy.

HERDING SOCIETIES

Herding societies are in many respects the direct opposite of forest horticulturalists. They are usually the most nomadic of primitive societies, they occupy arid grasslands rather than rain forests, they have a nearly total commitment to their animals, and their sociopolitical system is nearly always that of a true hierarchical chiefdom rather than of egalitarian villages and tribal segments.

The military advantages of herders

A society largely committed to herding has military advantages that a settled agricultural society does not have. If military power is important to survival, it will increase the commitment to the herding specialization, mainly because of the advantage conferred by mobility. This increased commitment, however, will result in the gradual loss of certain previously acquired material developments such as weaving, metalworking, pottery, substantial housing and furniture, and, of course, variety in the diet. Wealth is a burden in such societies. Successful nomadic pastoralists normally have some kind of symbiotic relationship to a settled society in order to acquire goods they cannot produce themselves. The symbiosis may be through peaceful trade. But often the military advantage of the pastoralists has led to raiding rather than exchange.

The best known and purest pastoral nomads are found in the enormous arid belt from Morocco to Manchuria, passing through North Africa, Arabia, Iran, Turkistan, Tibet, and Mongolia. They include peoples as diverse as the Arabized North Africans and the Mongol hordes. Other less specialized and successful pastoralists include the Siberian reindeer herders, cattle herders of the grasslands of north-central Africa, and the Khoikhoin and Herero of southern Africa.

Classic, full pastoralism with its powerful equestrian warriors seems to have developed around 1500 to 1000 BC in inner Asia. This relatively late full-scale pastoralist specialization may have resulted from population pressure. Horticulture mixed with domestication of animals seems to have predominated until even the least cultivable zones were filled. When warfare became endemic in such zones, many groups were forced to become fully nomadic in the arid grasslands. They might have been the losers, pushed out of their homelands, only to discover later the military power that accrued to the pastoral way of life. Thus, the victims became victors.

The full pastoralism of inner Asia requires the care of animals—including varying combinations of horses, cattle, camels, sheep, and goats—kept in ecological balance with grazing conditions over an enormous area. In some regions, however, the people may depend on a single animal species. In Arabia it is the camel (although most tribes in Arabia or North Africa also keep horses), and in east-central Africa some peoples specialize exclusively in cattle. Among these there is sometimes found a complete symbiosis between a tribe of herders and an adjacent tribe of horticulturalists to the point that they resemble a single society composed of two specialized castes, the herders occupying the superior position.

There are many part-time herding societies and many that have merely borrowed herding techniques. The reindeer breeders of the Siberian tundra have learned to apply to reindeer some of the methods of the horsemen farther south, but hunting remains their main subsistential activity. In the Argentine pampas, Indians learned to domesticate and ride the Spanish horse, which they used to hunt the rhea bird and the wild herds of Spanish cattle. The Navajo and other Indians of the American Southwest have exploited the sheep brought in originally by Spaniards, but mostly as a source of wool for blanket and rug weaving. Llamas and alpacas were domesticated in the South American Andes, but no independent pastoral society ever emerged there.

Fully committed pastoralists manifest a considerable degree of cultural uniformity. In economics, social organization, political order, and even in religion, their livelihood with its functional requirements has ironed out what must have been considerable cultural differentiation among such disparate peoples as Mongols, Arabs, and African Negroes.

Cyclical routes of the pastoralists

The wanderings imposed on pastoralists by the necessities of forage and water tend to be cyclical and to follow long-established routes. The cycles are usually seasonal: to the lowlands in winter, to highlands in summer in temperate zones, to more arid areas in the wet season, to more watered regions in the dry season, and so on. Frequently the seasonal moves are accompanied by cultural and organizational changes. For example, a large group may draw together to pass through hostile territory and disperse later when in their own land; frequently the lush (normally wet) season brings the pastoralists together for ceremonies, trade, and fun, while the dry season requires dispersion and arduous work (as in digging deep wells to water the animals). Anthropologists call such established cyclical movements "transhumance orbits."

Since pastoralists live in so many different environments and since even the same society varies from season to season and in response to wider spaced drought cycles, it is reasonable to expect great variations in population density. These factors, of course, affect political organization. Nomadic pastoralism lends itself to wide fluctuations in the size of political units, political cohesion, and degree of centralization.

The elementary unit of organization is the patrilineally extended family, frequently an elder patriarch and his sons and their families. In addition, if some degree of primogeniture (*i.e.*, the eldest son inheriting most of the decision-making power for the group) prevails, and if it is extended to include other groups in terms of putative birth order and patrilineal descent, the basis of the pastoral social organization is established. This social structure has been called the "conical clan" (for its hierarchical shape). It is a characteristic social organization of chiefdoms everywhere. Its capacity for waxing and waning, fusion and fission, has obvious advantages, especially when a brief makeshift political ordering of a very large horde is militarily necessary. But the large organizations cannot maintain themselves for very long, since they easily split into their parts.

It has been noted that herders are likely to raid settled villages. But herders frequently raid each other as well. Livestock is wealth and can be exchanged for other forms of wealth—including wives. Stock raiding, like most forms of aggression, has two facets: one seems to be to replenish one's wealth at a stranger's expense; the other is to warn strangers against encroachment. But a raid frequently leads to retaliation and then to counterretaliation, until such raiding societies gradually become hereditary enemies.

The militarism of herding societies has played a major role in history. As wealthy agricultural civilizations developed in the Fertile Crescent of the ancient Middle East, in the Indus River Valley, and at the middle bend of the Huang Ho in China, they became easy prey for nomads. Indeed, it is likely that urbanization was stimulated for defensive reasons because of the dangers posed by nomads. These dangers may also have stimulated the formation of

legal and governmental institutions in sedentary societies threatened by the pastoral raiders.

Trend to ancestor worship

To the extent that pastoral nomadic societies achieve wealth and success in herding and in war, they tend to solidify and extend their chiefdom structure. They also add to their religious organization a hierarchical principle together with the content known as ancestor worship. Much of the mythology by which a primitive people explains itself and its customs comes in this way to have an ingredient familiar to readers of the Old Testament—the lengthy story of who begat whom and in what order.

Increased dependence on herds, particularly dependence on one particular species, such as cattle, horses, or camels, is reflected in much of the ideological and ritual content of religion. Sometimes the significance of herding leads not only to the glorification of herds and herding but even to a religious taboo against planting. Some Mongols, so quintessentially pastoral, believe that plowing and planting defile the earth spirit. Among the Nuer, as among other African cattle herders, horticulture may be practiced in time of need, but it is considered degrading toil whereas herding is a very prideful occupation. The ethnologist of the Nuer, E.E. Evans-Pritchard, wrote:

> They are always talking about their beasts. I used sometimes to despair that I never discussed anything with the young men but livestock and girls, and even the subject of girls led inevitably to that of cattle.
>
> (From E.E. Evans-Pritchard, *The Nuer;* Oxford University Press, London, 1940)

(E.R.Se.)

PEASANT SOCIETIES

The one remaining category of nonurban society is that of the peasantry. Peasants are not nomadic but sedentary (thus distinguishable from both hunting-gathering societies and pastoralists); they are not horticultural tribal societies but more intensively and fully agricultural; and neither are they urban, like populations who lived in the centres of the classic civilizations.

Although writers on peasantry have not agreed on a precise definition, accounts of peasant cultures are likely to include these characteristics: peasant communities tend to be small, tradition bound, and resistant to change. Moreover, and perhaps most significantly, peasant societies are "part-societies" or "part-cultures" in relation to some larger civilization, colony, urban centre, state, or elite class. In this relationship the peasant occupies the inferior position because rural isolation tends to make him ignorant and no match for the sophisticated urbanite, and poverty keeps him dependent generation after generation. It is not simply that the peasant is somehow "exploited" (a difficult point to determine in most cases) but that his village is normally small, poor, ignorant, and backward compared with the urban centre. Horticultural tribes, by contrast, though living in even smaller villages and greater poverty and ignorance, possess in some sense a complete culture. What seems universal is the peasant's low status, with its concomitant ascription of poverty and ignorance, in contrast to other parts of the same culture.

Historical and geographic survey. Peasantries emerged with the urban revolution by about 4000 BC in Mesopotamia and about 1000 BC in Middle America. Some agricultural villages by then had begun to become cities, thereby initiating the process that gradually led to the formation of the empires of classical civilization.

Peasants in the empires of classical civilization

One major significance of the classical empire was that it could protect and thus politically incorporate, at least in some areas, scattered villages of simple cultivators. These outlying agricultural villages could not have survived without internal pacification (in the law-and-order sense) and without some kind of frontier militia. In exchange for such protection the rulers of the urban centre exacted heavy tribute from the peasantry. They soon realized that the price of the protection they extended to the peasants could easily be increased to the point of virtual expropriation. As a result, the peasants were reduced to the barest subsistence level. The urban rulers, by contrast, steadily advanced toward a literate culture, thereby widening the gulf between the city elite and peasantry.

In the course of time the preindustrial urban centre, with its statelike protection and intervention in the lives of peasants, made it possible to extend agricultural domains, usually as peasant holdings, into pastoral or other "wild" territory. An enormous part of the world's population became peasants as primitive peoples and nomads were dominated and displaced or transformed.

In the 20th century, with the rise of modern science and industry, peasants are being rapidly displaced in all of the so-called developing or modernizing parts of the world. To understand what peasants are, it is helpful to contrast them with what they are not—farmers in an industrialized world. The modern farmer, operating on a cost-accounting basis, has little in common with the peasant family or villager, to whom the tilling of the soil is a traditional way of life rather than a large-scale enterprise.

Distinction between peasant and farmer

Peasants could not simply turn into farmers primarily because they lacked the capital. In some parts of the industrialized world, such as Great Britain, central France, and the Low Countries, peasant villages managed to survive by maintaining a low standard of living and long working hours and often by developing some special handicraft for sale as folk art. More often, however, peasants became hired workers in the fields, or they migrated to the cities or overseas to the Americas.

Although there are no peasants in the United States and Canada, except for a few widely scattered villages of French Canadians, Appalachian mountaineers, Southern sharecroppers, and perhaps Pueblo and Navajo Indians, peasantries are still extant in large numbers in Europe, the Middle East, West Africa, southern and eastern Asia, and Latin America. Peasant cultures in these disparate regions vary considerably, depending on both ecological and historical factors. (E.R.Se./Ed.)

Types of peasant societies. *The community of self-serving households.* Though peasants are usually thought of as living in small, close-knit communities huddled against outside danger, they sometimes are so well-protected in mountainous or insular isolation that they feel secure enough to live more independently. In such circumstances, they dwell in scattered households in close proximity to the land they cultivate. They require a market centre of some sort where they may exchange goods and services. The Irish countryman, the isolated *fermier* of the French Massif Central, the Scottish crofter, the Paraguayan *campesino,* and the Brazilian *caboclo* are examples of such independent peasants. Occasionally the same people will be found living in close communities and also in scattered, more self-sufficient households. In the state of Michoacán in Mexico, for example, some of the tightest and closest knit communities to be found anywhere on Earth ring Lake Pátzcuaro, in immediate proximity to the large modern market town and tourist centre of Pátzcuaro. These are the fishing-, agricultural-, and handicraft-specialist villages of the Tarascan Indians. But many more thousands of Tarascans also live scattered in the adjacent mountains, making only infrequent visits to the market centres.

The village with internal specialization and exchange. In certain times and places peasant villages have been able to develop considerable self-sufficiency by creating part-time specialists and even full-time professional occupations. Such a development, however, presupposes an intensive agriculture in support of a fairly large population in order that the specialists may be kept fully occupied. The best examples of this kind of village are found in India, in the European medieval manor, and in some Latin-American haciendas.

Hindu villages

The most distinctive, as well as the most clear-cut, specialization occurs in Hindu India, where a typical village may contain as many as 2,500 people. The professional specialties are pottery manufacturing, stone working, barbering, trading, weaving, laundering, and herding. All of these occupations are carried on by separate castes, to which should be added the "twice-born" caste, the Brahman, or wise-man priest, though this is more of a status than an occupation.

The specialized services of the various castes often are rendered without any immediate payment or return service. The occupational castes all have an obligation to

provide their services. The full-time peasant agriculturalist, for example, expects a new plow or hoe from the carpenter, a pot from the potter, haircuts from the barber, and so on. After the semiannual harvest the peasant distributes appropriate shares of produce to those who have served him.

The caste system of occupations largely determines the status of individuals, but there are ways to attain higher status by acquiring wealth or political office. A wealthy landowner of low caste will continue to observe all the traditional attitudes of deference to those of higher caste; yet his opinion may be important and his power considerable in other than direct interpersonal dealings. And, of course, high and low status may be earned within a given caste depending on individual skill and personality.

Land ownership and tenure patterns are variable and complex. There are owners of large holdings who hire labour by wage or by shares. The majority are family-owners and workers of small plots, but large numbers of agricultural workers are landless, working only for others. Many families own some land and at the same time work other plots by shares or for wages. The usual peasant holding is worked jointly by a father and his sons. When the father dies, the land, stock, and implements are distributed equally among the sons. This practice is the major cause of the small size of the individual peasant holdings.

Many Indian peasant villages are exogamous (marrying outside), which results in ties among several villages as a consequence of giving and receiving wives. In such cases, every person participates in a social network outside his village to a greater extent than he associates with persons of other castes within his own village. These regional relationships are the means by which a common culture is diffused over a wide area. Hindu peasant villages are less alike the farther they are from each other, yet vast areas of rural India are remarkably homogeneous in culture.

The medieval manor

The European feudal estate also tended toward economic self-sufficiency in its local specialized occupations but was unlike the Hindu peasant village in several respects. For one thing, there were no castes. The aristocrats considered both their own and the peasant class to be permanent, God-given arrangements of hereditary status. Thus, to the extent that membership was in fact static, these classes were like Hindu castes (which have frequently been defined as "frozen classes"). But the other occupational classes of medieval times were not so castelike, although a tendency existed for son to succeed father. The occupational guilds resembled, to a certain extent, the wide geographic relationships of the Hindu castes. At the time of greatest stability in the European system, the social and political differences from Hindu practice were perhaps largely those of degree.

Other differences were enormous. Whereas India is overcrowded, medieval Europe, between the 11th and 15th centuries, was almost a wasteland by comparison. In fact, the existence of vast tracts of forest lands gave urgency to the problem of law and order; large groups of outlaws and predators could easily hide out. The essentials of the feudal system were master-client relationships: between kings and nobility and between the nobility. The superior individual gave protection to his clients, who in turn provided crops or services (especially labour and military duty).

Seigneury

The institution most typical of medieval society was the local seigneury, which may be defined as an estate comprising a group of people subjected to a single master. The land in such a system was of two kinds. One was the large home-farm, cultivated under the immediate direction of the seigneur or his supervisors. The other part of the seigneury consisted of various small-to-middle-sized holdings whose tenants occupied and cultivated them freely under the seigneur's protection in return for helping him in the cultivation of his demesne.

There were essentially three kinds of labourers: (1) the tenure holders, who owed regular services to the demesne; (2) wage labourers, normally paid in kind, unless they were imported labour to help out at specific occasions such as the grape harvest; and (3) workers housed and provisioned by the demesne. These workers are called prebendal in English (French *provendiers*) because they were provisioned and housed at the master's expense. The only difference between a prebendal worker and a slave was the freedom of the prebendal worker to leave if he was dissatisfied.

The tenure holder, or peasant, owed the seigneur two basic obligations, rent and services. Rents were highly variable, but services were usually still the greater burden. The basic services were agricultural labour on the demesne land, military duty, and craftwork. Agricultural labour, for example, might be calculated as three man-days a week per tenure holding. Since a family on a holding might be quite large, the three days could be divided among several men. Military duty would be highly variable because it would be a simple response to emergency—ordinarily an "all hands" response.

Craftwork was divided among peasants who had some skill passed on from father to son, especially metalworking. Spinning and weaving, wine making, carpentry, and sometimes milling and baking were duties divided among certain, but not all, peasant families. Probably most craftsmen worked at these tasks only part of the time in addition to the basic form of work.

The crafted products did not pass from peasant to peasant or between different specialists but were usually paid to the seigneur who reassigned them to others. This kind of indirect passage of goods from producer to centre and thence to ultimate consumer is the essence of the redistributional system described earlier as characteristic of chiefdoms. It is a way by which a holder of power can muster goods and serve his people at the same time. In political as well as economic structure, the resemblance of the seigneury to a primitive chiefdom is remarkable.

The seigneur was thus not simply a landowner or an exploiter of labour. He was a leader of men whose political-military status was highly direct and personal. He had command over his tenants, and the system would not have worked unless his subjects generally believed in and accepted him. His protective function gave rise to the seignorial court, which was the recognized place for a hearing of pleas and complaints. All in all, the seigneur served his people in many necessary ways, and they served him in others.

Naturally, the asymmetrical power relationship between seigneur and peasant sometimes resulted in attempts by seigneurs to multiply the services or benefits due them. On the other hand, the peasants, if numerous enough, often found ways to resist. But the power of the seigneurs presumably lay originally in their ability to allow or prevent the occupation by peasants of land under their military power. Similarly, peasants at certain early and insecure epochs might want the security of hereditary tenure; at other more secure and prosperous times, they might want freedom to leave.

By the 12th and 13th centuries in France every tenant was either free or a serf. The norm among free tenants was to be bound to the seigneur only because of their occupation of the land. If the tenant left, all obligations both ways were broken. On the other hand, the serf was not free to leave the land. Otherwise mutual dues and obligations were the same.

The hacienda

Another form of agricultural self-sufficiency is exemplified by the hacienda. In the early colonial period of Latin America the hacienda combined the Iberian and American Indian systems of land use. Pre-Columbian Indians in large areas of Latin America (from Chile north through the Andes and in Middle America) were densely settled on communal village holdings under the suzerainty of absentee aristocratic Indians. Other areas of Latin America were inhabited by more primitive tribes of slash-and-burn horticulturalists and nomadic hunter-gatherers. During colonial times in the areas of densely settled Indian population, the leading Spaniards were granted political control over designated villages. They were allowed to tax the Indian families and in return were supposed to protect them and educate them in the Roman Catholic faith. Sometimes Spaniards were rewarded by the crown with enormous tracts of land, latifundios, usually in areas of lesser population where large-scale herding would be the primary economic resource. Indian labour was also exploited in gold and silver mining and in workshops (*obrajes*).

The economy based on the exploitation of unskilled Indian labour was eventually disrupted by disease. Indians had no immunity to several commonplace European afflictions such as smallpox, typhoid fever, measles, and malaria. Numerous disastrous epidemics occurred, and by about 1600 both Spain and its richest New World possessions were in rapid economic decline.

Meanwhile, a new form of rural estate came into being as the economy of town and city, workshops, mines, and commerce was depressed. A large, privately owned estate could withstand monetary and commercial crises by becoming increasingly self-sufficient. The estate was manned by impoverished Indian workers who needed security and protection. The workers were usually paid in kind, enough for bare subsistence and given credit (against the promise of future labour) for the purchase of other necessities. This debt peonage was the foundation of a permanent labour supply, resembling the serfdom of medieval Europe.

The hacienda had a permanent group of peons settled on its lands, allowed to farm small plots for themselves. There were also house servants, some of whom might reside in the master's home. Other Indians might be residents of neighbouring villages but dependent on the hacienda for protection and often for grazing rights on fallowed rangeland claimed by the hacienda. A hacienda with numerous dependent villages on its periphery could muster a large labour force when needed and not employ it when not needed. The permanent debt peons, however, were more closely bound up in the everyday life of the hacienda. Like the European serf, the peon in difficult times probably welcomed the security of such an arrangement.

The hacienda probably was never completely self-sufficient, but it could take care of its own people in many ways. Large haciendas, some with thousands of peons, could afford numerous specialists, such as metalworkers and leatherworkers, weavers, bakers, masons, carpenters, and sometimes even a resident priest. There might also be a jail and a whipping post. And just as in European seignorial law, the master adjudicated disputes and meted out punishment. The economy of the specialized crafts resembled the European redistributional system insofar as the planning, commissioning, and delivery of all benefits were centralized under the hacienda master and his agents.

Virtual bondage of tenants

Although debt bondage no longer exists in Latin America, the tenant worker on the remaining large haciendas in some of the Andean areas seems as closely bound to the soil as peasants ever were. The Chilean tenant is legally free to move as he pleases, but he cannot, in fact, usually do so. He works his ancestral land, which he understands belongs to the hacienda, whose owner he has been conditioned all his life to regard as his master and protector. Were the worker and his family to leave, the other haciendas would not accept him. And since there is no vacant fertile land he could not become a squatter. Most peasants fear the city, which is already filled with the unemployed younger sons of peasants.

In Mexico, it was not until well into the 20th century that the hacienda system began to yield to modernism and more liberal laws, and the hacienda became increasingly commercialized. But earlier the peasant could not improve his position, legally or economically. By the end of the regime of Porfirio Díaz in 1911, the concentration of ownership of land in the hands of a few hacendados was greater than in any other Latin-American country. But the payment for agricultural labour had not risen appreciably since 1792. Over the same period the price of maize had increased 179 percent and that of beans 565 percent.

The closed regional market system. A kind of regional self-sufficiency may be seen among peasants in the Middle American highlands and the Andes, in parts of Indonesia, and in West Africa. These are nearly self-sufficient regions embracing peasant hamlets and villages that trade with each other, usually on a periodic market day or fair. These villages are typically cohesive and tend to be self-governing through ritual and religion. The relations of peasants with the outside world are usually mediated by the community (or its officials), except in the peasant market, where frequently some kind of middleman or representative of a store sells items not produced in the region itself.

The highland Indians of Mexico and Guatemala

The highland Indian communities, especially in Mexico and Guatemala, are quintessentially of this type. The inhabitants of the region are Indians (although there is a heavy overlap of Old Spanish custom, dress, and a folkish variant of Spanish Roman Catholicism). They all speak the same Indian regional dialect. They occupy such a distinctly inferior and helpless position in relation to the outer society that intermediaries of some sort are needed, and as a consequence of the felt inferiority they act toward outsiders in an extremely withdrawn manner. This withdrawal trait of the Indian peasantry has been appropriately labeled the "*encogido* syndrome," meaning a nearly utter lack of self-confidence.

The Indian communities that have legal ejidos (communal holdings) as well as small family properties are not usually subject to outside landowners. Thus, the *encogido* syndrome derives not from any inferior position of the peasantry to a resident owner (as in the hacienda system) but from the simple fact of ethnic stratification. These Indians feel themselves in an inferior position to everyone else in the whole outside world, that is, inferior to everybody except others designated as Indians. And they are usually also inferior in visible ways: extremely poor, uneducated, and ignorant of the manners and customs of the nation's urban citizenry. They have responded by withdrawing into their own community, which only serves to continue or to exacerbate the inferior condition, since much of it is caused simply by economic and social isolation from the main currents of national life.

Within the community of Indians extreme egalitarianism prevails. Prestige is won only in community service, which means giving more than receiving—a pattern very much like that of general reciprocity of primitive society. Giving takes the form of subsidizing one of the traditional fiestas of the community, an obligation that may be expensive in food, liquor, candles, and fireworks. Families work for years to get up the capital to sponsor a magnificent festival, at which they not only spend their savings but go into considerable debt. Lavishness in money and labour equals love (of the community); the poverty of an individual family may be accompanied by the highest prestige. This bears a resemblance to the Big Man system of Melanesia, where prestige is also linked with lavish giving.

Marketing behaviour

The economic egalitarianism of the village does not rule the periodic regional market. There the family, or its agent, tries to maximize its gains. Outsiders who see more of the marketing behaviour than of the more pervasive social economy within the individual villages are often misled by the ferocious haggling and cheating. Many regional markets are held in a smallish city of the national, non-Indian sort. The economically important market is the one in which the Indiáns exchange their own products with each other, yet it may be overshadowed by the market in which Indian handicrafts are sold to outsiders. Town stores may display their own wares in stalls at the market, and the carrier-middlemen may have brought materials from a considerable distance to sell where such items are rare and will bring a better price. And the same middleman (often simply the owner of a pickup truck) may buy materials that are abundant at one market for sale in another. In Mexico, the weekly Tarascan market in Pátzcuaro or the Otomí at Ixmiquilpan or, in Guatemala, the Mayan markets at Chichicastenango or Panajachel are large and complex, incorporating all of the above elements.

Close-knit peasant communities do change, of course; but it is their resistance to change that commands attention in modern times, when virtually all other institutions are committed to rapid change. Because the peasant community is a rigid structure, the individuals who want change and have the means or capacity to carry it out simply leave the village to find their place in some mixed community. In some peasant communities this is not possible. Thus, in densely settled central Java opportunities for the surplus peasant population to adapt to other modes of life were few. As population increased, putting stress on the traditional network of communal villages, the community tried to fit more people into the traditional system. The social patterns grew more elaborate but remained traditional; cooperative labour and tenancy institutions became

more intricate but otherwise did not change. Just as in the Latin-American Indian commune, egalitarianism continued on a basis of what has been called shared poverty.

In West Africa peasant society is based on full-time intensive agriculture, with a considerable amount of craft specialization and a large amount of trade carried on in great markets. In ancient times the more populated areas were organized as chiefdoms and primitive states, which exacted a tribute or tax from the agriculturalists in exchange for their protection and regulation. Intensive cultivators produce mainly for their own consumption, but with a frequent surplus or specialized handicraft to trade in the market. In modern times, they may produce surpluses to trade with a middleman representing an exporter. African villagers traditionally have been politically dependent on some hierarchical chieftains or patrimonial retainers. But they do not, like peasants elsewhere, feel themselves to be different from or inferior to any other class or culture. Nor are they so regarded by the urbanites with whom they come in contact.

General characteristics of peasant societies

One characteristic of the peasant economy is that the production unit is normally the family. But this does not mean that families are all the same size. Mainly, technical and economic requirements tend to govern the size of the family, which ranges from large three-generational extended families down to the nuclear unit of one set of parents and their unmarried children. Inheritance patterns tend to reflect the requirements of the agricultural operation. Whether the land is split equally among the heirs or passed on as a single unit (commonly through the eldest son) depends on whether farming requires large holdings or whether a small, intensively farmed area is sufficient. In some historical instances, the ecological determinant of the size of holdings has been contravened by ideology or law. For example, the Code Napoléon required that agricultural holdings be inherited equally, with the result that when the fragments of land were obviously becoming too small the French peasants responded with one of the most drastic reductions in the birthrate in all of recorded demographic history.

Some villages, notably among Latin-American Indians, are quite communalized. Individual families work plots of land, but it is the community as a whole that makes the important decisions. Other peasant societies with more independent households find numerous occasions for cooperation and labour exchanges among families. One widespread means of establishing a network of reciprocal obligations and trust within a peasant community is through ritualized ties of fictive kinship, such as the godparenthood common throughout most of peasant Europe and Latin America (in Spanish it is co-parenthood—*compadrazgo*). Other forms of fictive kinship are the familiar blood brotherhood of Balkan Europe, the *mit* of Nepal, and the *oyabun-kobun* of rural Japan. (E.R.Se.)

Urban cultures

DEFINITIONS OF THE CITY AND URBAN CULTURES

Research on urban cultures naturally focuses on their defining institution, the city, and the lifeways, or cultural forms, that grow up within cities. Urban scholarship has steadily progressed toward a conception of cities and urban cultures that is free of ethnocentrism, with broad cross-cultural and historical validity.

Well into the 20th century conceptions of the city often proceeded as if there were only one authentic or typical form. From his research on the city in Europe's Middle Ages, Henri Pirenne, for example, argued in *Medieval Cities* (1925) that two characteristics were fundamental to the development of an urban culture: a bourgeoisie, or middle class, that depends on trade for both wealth and political autonomy from nonurban feudal power holders; and a communal organization of the urban citizenry that creates the municipal integration necessary to free the city from control by local feudal lords or religious authorities. Although it has often been taken as a general definition of the city and urban culture (whence the commonsense notion that cities must fulfill commercial functions), Pirenne's formulation was deficient because only the European medieval city and its burgher culture were taken as typical of the "true" city.

Max Weber's definition of the city

Max Weber in *The City* (1921) provided another definition of the city, similar to Pirenne's, when he contrasted "Occidental" with "Oriental" urbanism. According to Weber, five attributes define an urban community: it must possess (1) a fortification, (2) a market, (3) a law code and court system of its own, (4) an association of urban citizenry creating a sense of municipal corporateness, and (5) sufficient political autonomy for urban citizens to choose the city's governors. Weber believed that Oriental cities rarely achieved these essential characteristics because familial, tribal, or sectarian identities prevented urban residents from forming a unified urban citizenry able to resist state control. Even with regard to the Occident Weber's definition would exclude almost all premodern cities, for the urban autonomy he required existed only in northern Europe and Italy and, even there, for very short periods of time at the end of the Middle Ages. The result was an overly limited conception of urban cultures, from which it was extremely difficult to generate a cross-culturally valid understanding.

In the 1940s Robert Redfield, strongly influenced by Louis Wirth and other members of the Chicago school of urban ecology, conceived of the urban as invariably impersonal, heterogeneous, secular, and disorganizing. In the folk-urban model, as set forth in his article "The Folk Society," Redfield contrasted this image of city life with an image of the folk community, which he characterized as small, sacred, highly personalistic, and homogeneous. He presumed that as individuals moved from folk community to city or as an entire society moved toward a more urbanized culture, there would be a breakdown in cultural traditions. Urbanizing individuals and societies would suffer from cultural disorganization and would have higher incidences of social pathologies like divorce, alcoholism, crime, and loneliness.

Redfield's conception of the city depended on the urban research carried on by sociologists in American industrial cities, predominantly Chicago. He ethnocentrically assumed that their findings could be generalized to all urban cultures. Subsequent research indicated that this conception was in many respects wrong even for American industrial cities. In spite of being generally ethnocentric and specifically inadequate for American cities, this conception still holds sway over much popular thinking, which conceives of cities, in all cultures and all times, as centres of bohemianism, social experimentation, dissent, anomie, crime, and similar conditions—whether for good or bad—created by social breakdown.

Gideon Sjoberg (*The Preindustrial City, Past and Present,* 1960), in the next step toward a cross-culturally valid understanding of cities, challenged this conception of urban culture as ethnocentric and historically narrow. He divided the world's urban centres into two types, the preindustrial city and the industrial city, which he distinguished on the basis of differences in the society's technological level. Preindustrial cities, according to Sjoberg, are to be found in societies without sophisticated machine technology, where human and animal labour form the basis for economic production. Industrial cities predominate in the modernized nations of western Europe and America where energy sources from fossil fuels and atomic power phenomenally expand economic productivity. For Sjoberg, preindustrial urban culture differed markedly from its industrial counterpart: the preindustrial city's neighbourhoods were strongly integrated by personalistic ties of ethnicity and sectarian allegiance; it maintained strong family connections, and social disorganization was little in evidence; churches or other sacred institutions dominated the skyline as well as the cultural beliefs of the urban place; and the major urban function was imperial administration rather than industrial production.

Preindustrial and industrial cities

Although Sjoberg's conception of a preindustrial urban type was a major improvement over previous urban definitions, it too suffered from overgeneralization. Sjoberg collapsed urban cultures of strikingly different sorts into a single undifferentiated preindustrial city type—for example, the cities of ancient empires were conflated with

present-day urban places in the Third World. Past urban cultures that did not readily fit the Sjoberg conception, such as the autocephalous (self-governing) cities of early modern Europe, were disposed of as temporary and unusual variants of his preindustrial type rather than important varieties of urban culture.

In "The Cultural Role of Cities," Robert Redfield and Milton Singer tried to improve on all previous conceptions of the city, including the one Redfield had himself used in his folk-urban model, by emphasizing the variable cultural roles played by cities in societies. Redfield and Singer delineated two cultural roles for cities that all urban places perform, although with varying degrees of intensity and elaboration. Cities whose predominant cultural role is the construction and codification of the society's traditions perform "orthogenetic" functions. In such urban cultures, cadres of literati rationalize a "Great Tradition" of culture for the society at large. The cultural message emanating from Delhi, Paris, Washington, D.C., and other capitals of classic empires or modern nation-states functions to elaborate and safeguard cultural tradition. By contrast, cities whose primary cultural role is "heterogenetic," as Redfield and Singer defined it, are centres of technical and economic change, and they function to create and introduce new ideas, cosmologies, and social practices into the society. In cities like London, Marseille, or New York, the intelligentsia challenge old methods, question established traditions, and help make such cities innovative cultural centres.

The city's orthogenetic and heterogenetic functions

Continuing Redfield and Singer's concern for the cultural role of cities within their societies, Paul Wheatley in *The Pivot of the Four Quarters* (1971) has taken the earliest form of urban culture to be a ceremonial or cult centre that organized and dominated a surrounding rural region through its sacred practices and authority. According to Wheatley, only later did economic prominence and political power get added to this original urban cultural role. Wheatley, following Redfield and Singer, established that any conception of an urban culture had to be grounded in the cultural role of cities in their societies; research must specifically address how the urban cultural role organizes beliefs and practices in the wider culture beyond the urban precincts, and, consequently, how this urban cultural role necessitates certain lifeways and social groupings (cultural forms) in the city.

Beginning in the 1970s, David Harvey (*Social Justice and the City,* 1973), Manuel Castells (*The Urban Question,* 1977), and other scholars influenced by Marxism caused a major shift in the conception of urban cultural roles. Although they mainly worked on cities in advanced capitalist cultures, their approach had wide relevance. Rather than looking outward from the city to the urban culture as a whole, the new scholarship conceived the city as a terminus for cultural roles emanating from the wider culture or even the world system. Harvey, for example, linked major changes in American urban lifeways to the urban culture of advanced capitalism: for him, the growth of suburbia developed out of capitalism's promotion of new patterns of consumption in the interests of profit. Castells saw the city as an arena for social conflicts ultimately emanating from the class divisions within capitalist society.

This Marxist scholarship did not contradict the earlier emphasis on the city as the source of cultural roles so much as complement it. Studying the cultural roles of cities must include not only the cultural beliefs and practices that emanate from cities but also the cultural forms that develop within the city as a result of the impact of the urban culture on it. In this way scholarship can bring forward a cross-culturally and historically valid conception of cities, their cultural forms, and the urban cultures in which they are set.

TYPES OF URBAN CULTURES

The following typology of urban cultures depends on a conception of cities as centres for the performance of cultural roles found only in state-level societies. Such societies, in contrast to the nonurban cultures previously discussed, have inequalities in economic wealth and political power, the former usually evidenced by class divisions, the latter by specialized institutions of social control (ruling elites, government bureaucracies). Because cities do not occur in societies without state organization, the terms "urban cultures" and "state-level societies" are closely linked—the former emphasizing belief patterns, the latter stressing social organization in such societies.

State-level societies and urban cultures

State-level societies differ in the nature and extent of economic and political inequalities, and this variability accounts for the different types of urban cultures and cultural roles adduced below. The labels for the types of urban cultures denote the predominant cultural role played by cities in this urban culture—thus, "ritual city" or "administrative city." Obviously, cities in any society combine some amount of ritual role with administrative functions. The rationale for the labels used below, however, is that given particular constellations of inequalities, certain urban cultures come to exist and certain cultural roles of cities come to characterize or typify them. Thus, the label "administrative city" typifies the major (but not exclusive) cultural role played by cities in agrarian empires, whereas "industrial cities" represents the dominant urban cultural role in capitalist nation-states.

The typology below draws a major distinction between urban cultures that existed before the development of the world capitalist system in the 16th century and those that came after. Before the world capitalist system developed, state-level societies were not integrated in an economically unequal relationship. The advent of the capitalist world system led to a specialized world economy, in which some state-level societies represented the core and others represented the economically, and often politically, subservient periphery. Before the world system, urban cultures differed mainly on the basis of internal differences in political and economic inequality. After the world system, urban cultures, in addition, differed according to their placement in either the core or the periphery.

Urban cultures before the capitalist world system. *The ritual city.* Ritual cities represented the earliest form of urban centre, in which the city served as a centre for the performance of ritual and for the orthogenetic constitution and conservation of the society's traditions. Ritual was the major cultural role of such cities, and through the enactment of ritual in the urban locale, rural regions were bound together by ties of common belief and cultural performance.

The early forms of urbanism in the pristine civilizations of the Old World and Meso-America, which Wheatley refers to as "cult centres," conform to the ritual city type. Other examples of ritual cities can be drawn from ethnographies of the urban culture of the Swazi in southeast Africa, Dahomey in West Africa, and Bali before the Dutch conquest. In most areas of the world this form of urban culture was quickly succeeded by more complex types.

Ritual cities were found in urban cultures that have been called "segmentary states" or "primitive states." Such states had minimal development of class stratification and political coercion. Although segmentary states had rulers, such as a chiefly lineage or a priesthood, control over land and other means of production remained with clans, lineages, or other kin-based groups outside the rulers' domination. Political authority and economic wealth were therefore widely dispersed.

Limited political centralism and economic coordination meant that the ritual, prestige, and status functions of the state loomed large. Segmentary state rulers were symbolic embodiments of supernatural royal cults or sacred ritual ones. They—their courts and temples—provided a model of the proper political order and status hierarchy that was adhered to throughout the otherwise weakly cohered segmentary state. Through the awe they inspired, they extracted gifts from the rural populace with which to sustain their royal or priestly election.

The cultural forms of ritual cities centred on the cult centres, temple complexes, or royal courts that dominated their physical space and defined their urban role. As the rulers' habitation, the ritual city spatially embodied the role of the sacred and ceremonial in defining the urban culture. The everyday population of the city consisted of those bound to court or temple by family, official duties,

or craft and ritual specializations; at ceremonial times, people from the surrounding rural areas temporarily swelled the urban area. Therefore, rather than individualism, secularism, or impersonality, the calendrical round of state rituals, kingly ceremonies, divine sacrifices, sacred celebrations, feasts, funerals, and installations defined urban life, rendering it sacred, corporate, and personalistic.

The unifying effect of the ritual city

The city as ritual centre made for strong rural–urban solidarity. Because in the segmentary state power and wealth were dispersed rather than concentrated in the city, there existed no intrinsic antagonism between country and city. Consequently the orthogenetic message of tradition and sacredness broadcast from the city throughout the urban culture had a unifying effect, forging a solid rural–urban bond.

The administrative city. Like ritual cities, administrative cities were the habitations of the state rulers. Their major cultural role was to serve as the locus of state administration. State offices and officers had an urban location, from which they exercised a political control and economic exploitation of the surrounding rural areas quite unknown in ritual cities. Administrative cities also had a qualitatively different demographic and social complexity. They contained large populations, densely settled, often ethnically varied, with heterogeneous occupations. Such cities were nodes of communication and transportation and centres of commerce, crafts, and other economic functions for the surrounding countryside.

Administrative cities occurred in agrarian empires, state-level societies associated with the early civilizations of Hindu and Muslim India, China, and Egypt, as well as the Mamlūk Middle East, Tokugawa Japan, Alexandrine Greece, and other expansive territorial states before the advent of the world capitalist system. These states had rulers with great powers of political coercion, which they used to maintain a high level of inequality in wealth between the state ruling elite and the primary producers, the peasantry. This type of urban culture rested on how effectively the state could exploitatively control peasant agricultural productivity for maintaining the elite. The urban administrative cultural role was the major means to this end.

The administrative city brought together the political, economic, transport, and communications functions and institutions necessary for this rural rapine. For just as the state elite preyed on the peasant, so the administrative city's flamboyant architecture and monumental public works ultimately rested on what could be taken from the rice paddies of the Japanese cultivator or the wheat field of the Indian peasant. There also grew up urban populations that converted the wealth taxed from the rural area into a sumptuous life-style for the urban-resident state elite: artisans and artists, of various levels of reputation. This gave rise to the poor of the city and, often, institutions to help govern and subdue them, such as municipal governments. Merchants also were necessary to convert the peasant's grain payments into cash. Administrative cities commonly tried to restrain the wealth of urban merchants from fear that such riches might be converted into political power.

Growing discrepancy between urban and rural ways of life

As the links between coercive state and oppressed peasant grew stronger (that is, as the two became more unequal), the urban cultural practices (for the elite) became more separated from those of the countryside. The urban area concentrated a sophistication, an elaboration of custom and ideology that marked it off from the rural, which now was defined as rustic. Alongside the elaborate, the monumental, and the beautiful, which distinguished the administrative city's architecture, elite entertainments, and general cultural forms from those of the countryside, however, there was also an overwhelming poverty in the city's artisan and servant wards.

The administrative city had some of the properties commonly attributed to cities: it was a locale for cultural elaboration and monumental building, a repository of great wealth but also of extensive poverty, and a heterogeneous locale, both occupationally and in terms of ascriptive identities based on ethnicity, religion, caste, or race. But it was not disorganized or impersonal. Family, guild, and ethnic group framed the allegiances that defined the basic unit of urban cultural practice, the city quarter, which for the urban nonelite functioned with many of the characteristic cohesions of the peasant village.

The mercantile city. Mercantile cities appeared at the geographic margins or at times of dissolution of agrarian empires—for example, in medieval and early modern Europe, after a decentralized feudalism had fully replaced the Roman Empire. This urban type is thus a variant form that appeared, under particular conditions, in the urban cultures that also contained administrative cities. The mercantile city's links with the wider culture were disjunctive rather than, as with the administrative city, supportive. A class of powerful and wealthy merchants not completely beholden to the state rulers grew up in such cities and, left unchecked, could grow strong enough to effectively challenge the state rulers. This merchant class, and the mercantile cities it occupied, depended for their wealth and political autonomy on the profits of international trade, moneylending, or investment in cash cropping of export agricultural commodities (as, for example, vineyards and olive groves in the Mediterranean). The city produced wealth and capital in its own right rather than simply sucking it from rural agriculture. Such wealth provided an avenue for political power separate from that offered by the revenues derived from the peasantry. Often, therefore, urban magnates and state power holders or rural gentry stood in strong opposition, each trying to control—or absorb—the wealth and power of the other.

Mercantile cities varied in the extent of legal, fiscal, and martial autonomy they enjoyed. At their most developed, they conformed to the definitions of "true" cities provided by Weber and Pirenne. They enjoyed independent municipal government, sported urban fortifications, fielded citizen armies, and even subdued surrounding rural magnates. In less developed (generally earlier) mercantile cities, urban independence was not so great: for example, urban trading capital depended on intermarriage with rural magnates or came from rural moneylending. Even in such cases, however, rural resources were put to novel uses in the urban setting.

The cultural role of mercantile cities grew out of their independent economic productivity and their political autonomy. They played a very strong heterogenetic role. They were strongholds of a merchant class and other social strata based on acquired wealth, against the landed aristocracy of the agrarian empire. Because they were often under attack from the aristocracy, these cities came to symbolize freedom and social mobility: "city air makes one free." Being embattled, mercantile cities also became bastions of cultural innovation. Urban cultural form emphasized achievement, and urban politics involved shifting factional alignments. Given the volatility of commercial operations, leading families rose and fell rapidly, and plutocracies, quite fluid in membership, came to rule these cities. The poor artisans and small traders too were more independent than in administrative cities, and through occupational or sectarian associations, like guilds, they demanded and won political concessions.

Mercantile cities as seedbeds of cultural innovation

Although places of innovation, achievement, freedom, and mobility—traits that they share with industrial cities—mercantile cities were neither impersonal nor secular. The extended family was the major institution organizing business firms, political coalitions, and much elite social life. Other corporate institutions, like guilds and religious fraternities, joined city dwellers into highly personalized, ritualized associations that downplayed individualism and secularism in the city.

Given the commercial conditions and the difficult class oppositions that set the cultural context for mercantile cities, they proved evanescent and fragile, usually reverting under state intervention to administrative cities, in which the merchant magnates and their wealth came under the control of state rulers.

Urban cultures since the capitalist world system. Beginning in the 15th century, the Age of Discovery, Europeans carried the capitalist system burgeoning at home to distant places, whose labour and productivity were harnessed to the European core in an unequal, colonial relationship. The result was the capitalist world system, as Immanuel M. Wallerstein in *The Modern World-System* (1974) terms

it. There was increasing economic and productive specialization among the world's regions, as a pattern of unequal exchange developed between the industrial commodities of the advanced European nations (at the world system's core) and the raw materials from underdeveloped Asia, Africa, and the New World (at the world system's periphery). By the 18th century a worldwide urban culture had come into existence. It took variant forms of economic, political, and urban organization in the colonizing core and in the colonized periphery. Although the following discussion treats urban cultures in the core and in the periphery separately, it must be remembered that they—and the urban cultural roles that typify them—form an interactive unit.

The industrial city. Industrial cities appeared after the full development of industrial capitalism in the core nation-states of the late 18th-century world system. Their urban cultural role fit well with the capitalist economic order that came to dominate all other social institutions. Capitalism depended on the production of commodities through wage labour in the interests of capital accumulation. The city became a centre of such production processes and the location for the industrial factories in which this production most typically took place. It was also the residence for the other "commodity" necessary to its productivity, wage labourers. Ancillary urban functions—banking, wholesale and retail trade, transportation and communications nodality—grew up to expedite the factory production or the provisioning of the labour force.

Factories and wage labourers in the industrial city

Rapid population increase through in-migration characterized the growth of the industrial city. The most salient aspects of urban cultural forms grew up in the neighbourhoods that housed the newly urbanized labour. Populations with very different cultural characteristics came together in the city, such as the Irish in the British Midlands or the many ethnic groups that formed the urban American melting pot. Ethnic and racial ties often provided the links for migration chains, and they helped recent migrants find jobs, housing, and friendship in a new environment. These ties often resulted in ethnically segregated urban neighbourhoods among the working class.

Two contradictory patterns of organization and conflict characterized this urban population. One pattern grew out of the dense settlement of the working class in the industrial city. Residential aggregation helped organize large-scale working-class protest in the interests of better working conditions and wages. The other, contradictory, pattern consisted of ethnic or racial exclusiveness and competition within the working class. Ethnic or racial residential segregation often provided the base for competition among members of the working class for jobs and urban locations convenient to the workplace. Characteristically, one ethnic population in the industrial city guarded its neighbourhood against invasion by another—or, in times of rapid economic growth and social mobility, ethnic succession, wherein an upwardly mobile ethnic population would leave its neighbourhood to a newly urbanizing ethnic grouping, would occur. The retention or strengthening of ethnic or racial identities in industrial cities commonly took place under these conditions.

The industrial city is the terminus for two conflicting processes emanating from the capitalist character of the wider society: capitalist investment in urban property for profit making, and class conflict. The former process subjects the human and natural environment to the interests of capital accumulation; the latter makes for the formation of urban neighbourhood associations, ethnic associations, and other sorts of class alliances that organize local resistance to this profit taking. The city then becomes a battleground for these opposing forces. Castells in *The City and the Grassroots* (1983) has studied a range of social movements in present-day American and European industrial cities that arose in resistance to capitalist rationalization of the urban environment. The resistance can take different forms but includes attempts to preserve public services or public spaces for their use value against a capitalist rationality that would privatize and put a price tag on them—that is, this resistance aims at making municipalities rather than private enterprise responsible for provisioning good schools, recreational facilities, museums, and parks. Other forms of resistance consist of attempts to preserve the cultural identity of neighbourhoods and subcultures against residential blockbusting and attempts to develop neighbourhood decentralization so that the urban population takes control over its own living environment.

The mass-communications city. The industrial city, consonant with the rise and consolidation of capitalism in the western European and North American core nations, appears to be rapidly giving way to what has been termed the mass-communications city in the advanced industrial nations. Cities such as New York, London, Tokyo, and other metropoles increasingly perform a primary cultural role as centres of managerial control, based on high-technology mass communication and data processing, over far-flung manufacturing activities. Old urban manufacturing centres in the core of the capitalist system, like Birmingham, Eng., Detroit, and Glasgow, have declined as their role in industrial production has become less important.

The movement toward the mass-communications city has to do with changes in the urban culture of the core brought on by changes in the world system since the 20th century began. This development of "late capitalism," "monopoly capitalism," or the "welfare state," as it is usually labeled, depended on the investment of capital from the core to generate industrial production in the periphery, usually through the institution of multinational corporations. The cultural role of core cities is shifting away from manufacturing as they come to house the advanced means of communication and data analysis necessary to manage this worldwide industrial production.

The mass-communications city ceases to be primarily a habitation of the industrial working class. Instead, those working mainly in high technology industry and service (the middle class) define urban cultural forms. For example, suburbanization and gentrification, two characteristic urban residential patterns of the middle class, become important cultural forms in such cities. Both show the emerging importance of the new social class and the provisioning of new urban spaces (the suburbs) or the renovation of old ones (gentrified inner cities) for it. Again, these new urban locales represent the larger capitalist society, in that they are locales for profit making as well as arenas of class resistance. Harvey in *Consciousness and the Urban Experience* (1985) argues, for example, that the suburbanization process typical of American cities, especially after World War II, was motivated by the need to foster a new life-style of consumption to negate problems of capitalist overproduction. It also minimized class violence by spreading population out from the old, dense, inner-city neighbourhoods. These suburbs, however, once created in the service of capitalist profit making, can become the locales for resistance against further capitalist rationalization of urban space and against the inroads of welfare statism on local decision making.

Suburbanization and gentrification

As the mass-communications urban cultural role further develops in the advanced industrial societies and industrial production is exported, whatever urban manufacturing continues must meet the competition of imported commodities. Various new means of urban labour use develop to make production cost-effective. For example, manufacturing is left to the lowest strata of the urban population, either illegal migrants, such as Mexicans or Haitians in the United States, or the most underprivileged of the national population, such as American blacks, or foreign workers, such as eastern Europeans or Turks in France, who do not have full citizen rights. Often, manufacturing that once was done in factories is now done in homes as a way of minimizing costs, especially by avoiding government regulations and taxation. Thus, because they work at home or because they are illegal migrants or because they are subject to racial prejudice, the labourers have little legal protection and welfare support. In the face of this massive insecurity they depend on extensive mutual-aid networks, in which the poor share the risks of poverty among themselves. Their abject condition—and their attempts at security—mirror the practices of poor shantytown dwellers in neocolonial cities, as described below.

The colonial city. Colonial cities arose in societies that

fell under the domination of Europe and North America in the early expansion of the capitalist world system. The colonial relationship required altering the productivity of the colonial society in order that its wealth could be exported to the core nations, and colonial cities centralized this function. Their major cultural role was to house the agencies of this unequal relationship: the colonial political institutions—bureaucracies, police, and the military—by which the core ruled the colony, and the economic structure—banks, merchants, and moneylenders—through which wealth drained from colony to core.

Bombay and Calcutta under the British, the European trading cities in China and West Africa, the British East African and Dutch East Indian urban centres for the collection of plantation crops—from the 18th through the mid-20th centuries—represent this urban type. The core capitalist nations implanted colonial cities as new growths into preexisting precapitalist state societies in many world regions, just as they altered the societies by making them unequal participants in world capitalism. The resulting urban culture represented a novel amalgam of the core and the periphery, with qualities not found in either parent culture.

Amalgam of core and periphery

This new combination was most in evidence in the elite population of the colonial city and its cultural forms. For example, new classes and urban lifeways appeared among the indigenous population. Most of the time the cultural role of the colonial city required the creation of an indigenous urban lower-middle class of merchants, moneylenders, civil servants, and others who were educated to serve the colonial political and economic establishment. For instance, Thomas Babington Macauley, a British Indian administrator in the mid-19th century, hoped to create an elite through Western-style education that was "Indian in blood and colour, but English in taste, in opinion, in morals and intellect." The colonial educated lower-middle class often attempted to reform its culture in line with that of the colonizing power, most often through new urban institutions like schools, welfare associations, and sectarian or secular reform groups. A generation or so later, this class transformed by these urban institutions, commonly formed the leadership of nationalist, anticolonial movements. Thus, the colonial city, which began as an instrument of colonial exploitation, became a vehicle of anticolonial protest through this lower middle class and the cultural institutions, schools, newspapers, and other urban cultural forms it had constructed.

After World War II many new nations in Asia and Africa gained independence. Although no longer the direct political colonies of Western countries, these urban cultures and their cities continued in a dependent economic relationship with the advanced industrial nations.

The neocolonial city. The latest type of urban development in the periphery of the capitalist world system, or what is often called the Third World, is the neocolonial city. This urban type has arisen in relation to the development of monopoly capitalism and the mass-communications city in the core. Export capital from advanced industrial nations has created enclaves of industrial production in Third World cities, thus replicating in these urban places many of the cultural roles played by the industrial city in the core. There are urban factories and urban-resident wage labourers. There is a developing infrastructure of urban transport and communication by which these commodities and labourers are allocated. There is massive urban-ward migration from neighbouring rural areas.

The neocolonial city, however, does not exactly duplicate the cultural role of the industrial urban type precisely because of its dependent relationship with the core. One major difference is that the commodities produced in neocolonial cities generally are destined for export rather than for home consumption, except perhaps by a small home elite. The neocolonial city does not serve an indigenous hinterland; it serves the wider world economy. Its rural environs are important only because they provide a large and readily available labour supply.

Distinction between industrial and neocolonial city

The large-scale urbanization in the neocolonial city differs from the urbanization that characterized the industrial city earlier. It gives rise to what has been called the informal economy in these cities. The informal economy consists of urban services and products provided by the neocolonial city's poorest denizens, the petty hawkers, the shoeshine boys, the household help, the rag pickers, and others who form a class of petty commodity producers and sellers. The common image of these people is highly pejorative: they are marginal to the city, usually unemployed and often criminal, unmotivated and dysfunctional to urban life, characterized by a "culture of poverty" that, at the same time, makes them accept their wretched condition and keeps them in it. Their marginality is often said to be exemplified in the shantytowns, tin can cities, or squatter settlements that they build at the borders of the city and that blight it. This "myth of marginality" as Janice Perlman calls it (*The Myth of Marginality,* 1976) obscures the importance of shantytown inhabitants in defining the nature of the neocolonial city.

To compete successfully in the world market, commodities manufactured in Third World cities have to be less expensive than the comparable items produced in the core. Wage labour in the industrial sector of these cities is considerably cheapened because many services and small commodities that wage labourers require are supplied through the informal economy. As Larissa Lomnitz indicates in *Networks and Marginality: Life in a Mexican Shantytown* (1977), recent rural migrants and shantytown dwellers act as maids, gardeners, and handymen to the industrial workers and the middle class at costs well below what would be charged if the formal sector supplied these services (comparable to domestic labour and baby-sitting supplied well below minimum wage in the core nations).

The informal urban economy never provides security, and the inhabitants of shantytowns in neocolonial cities have had to develop cultural means of survival over the hard times that commonly befall them. Rather than being places of anomie, shantytowns are made up of highly intimate webs of relationship and mutual dependence, based on carefully fostered kinship, ethnic, sectarian, or friendship networks. These networks succor those temporarily out of money and provide some security for those otherwise economically unprotected, who have neither job security nor welfare institutions to fall back on, given the informal sector work that they do.

Shantytowns

These networks, which are in fact adaptations to the exigencies of neocolonial cities, often appear as survivals from the peasant or rural backgrounds of the shantytown dwellers—they are said to be "peasant urbanites" rather than truly urbanized, and this image incorrectly strengthens the notion of their marginality. The tribal identities found among recent urban migrants in African cities are actually instances of "retribalization," a strengthening or redefinition of tribal identity to form networks among urban migrants for mutual aid. Similarly, extended family networks may not disappear in the city; they became wider and stronger among Mexican shantytown inhabitants, for example. New sectarian identities can play an equivalent role: Bryan Roberts in *Cities of Peasants* (1978) shows that the growth of Pentecostal and other Protestant sects in Guatemala fulfills needs for mutual support networks in poor neighbourhoods and for those without kin ties.

Although shantytown inhabitants in the informal economy are impoverished and insecure, it is not certain that they can organize and struggle for better urban living conditions, as did wage labourers in industrial cities. Whereas some scholars have argued for the revolutionary potential of this class, others are persuaded that it does not form a proletariat and will not engage in revolutionary confrontation. The fact that the people who live in shantytowns are "self-employed" and do not enter a wage relationship with the urbanites whom they provide with services apparently limits class antagonisms. Furthermore, both the middle class and shantytown dwellers often perceive their real enemies as the Western imperialist nations or the national government said to be in league with international capital. This perception recognizes that the travails of all classes in the neocolonial city have more to do with external economic relationships in the world economy than class exploitation within the city.

CITIES AND CULTURES

The subject matter of urban anthropology

In the 1970s anthropologists debated whether they should proceed with micro-studies of the city's poor or its recent migrants—an anthropology "in the city," as it was called—or with macro-studies of the city as a whole—an anthropology "of the city." Ten years later the debate was resolved by a tide of studies that focused neither at the micro-level nor at the macro-level but rather at the links in between, that is, the webs of cultural, economic, and political relationship binding the shantytown, ghetto, or neighbourhood to the city and even beyond, to the world economy.

In urban cultures after the establishment of the capitalist world system these webs consist of the economic, political, and cultural strands linking mass-communications cities in the core with neocolonial cities in the Third World into a world system of unequal political and economic relationships. For precapitalist urban cultures these webs consisted of power and wealth inequalities and cultural domination within the urban culture. These different webs effect variant urban cultural roles and cultural forms.

Urban anthropologists in the 1970s also worried over the contribution their studies of urban cultures would make to the general anthropological concept of culture. Oscar Lewis initiated a debate about the nature of culture when he put forward his notion of an urban "culture of poverty." He believed the culture of poverty socialized the poor into political apathy, immediate gratification, broken families, and passive responses to their economic plight, and he argued that the poor could not lose this debilitating culture even if they ceased to be poor. A massive scholarly critique of the culture of poverty concept also exposed the limitations in the traditional anthropological conception of culture on which it was based. This critique argued that the poor's marginality was not a result of their internalized culture but rather of their abject material conditions given the world system (as in the case of the shantytown research cited above). In the face of this critique, the traditional notion of culture—that it was a weighty set of traditions compelling individuals to act in certain ways—gave way to a conception of the constant production of cultures (urban or nonurban) through continual human action—people working with their hands and minds—in response to the material conditions of everyday life. (R.G.F)

LEE and IRVEN DEVORE (eds.), *Kalahari Hunter-Gatherers: Studies of the !Kung San and Their Neighbors* (1976), and *Man the Hunter* (1969); LEWIS H. GARRARD, *Wah-To-Yah and the Taos Trail* (1850, reprinted 1982), an account of Plains Indian life; E. ADAMSON HOEBEL, *The Cheyennes,* 2nd ed. (1978); F.R. SECOY, *Changing Military Patterns on the Great Plains (17th Century Through Early 19th Century)* (1953, reprinted 1971), an analysis of the rise of Plains Indian nomadic equestrian societies; and PHILIP DRUCKER, *Cultures of the North Pacific Coast* (1965), an account of sedentary fishing societies. An analysis of the forms of economic exchange among those societies is HELEN CODERE, *Fighting with Property: A Study of Kwakiutl Potlatching and Warfare, 1792–1930* (1950, reprinted 1970). Pastoral societies are depicted by OWEN LATTIMORE, *Inner Asian Frontiers of China,* 2nd ed. (1951, reissued 1967); LAWRENCE KRADER, "Ecology of Central Asian Pastoralism," *Southwestern Journal of Anthropology,* 11(4):301–326 (Winter 1955); and E.E. EVANS-PRITCHARD, *The Nuer* (1940, reprinted 1974). The consequences of plant and animal domestication is discussed in ROBERT J. BRAIDWOOD and GORDON R. WILLEY (eds.), *Courses Toward Urban Life: Archeological Considerations of Some Cultural Alternates* (1962); and modern horticulturalists are analyzed by MARSHALL D. SAHLINS, *Tribesmen* (1968).

Important general works on peasant societies are ROBERT REDFIELD, *Peasant Society and Culture* (1956, reprinted with *The Little Community,* 1973); ERIC R. WOLF, *Peasants* (1966); EMMANUEL LE ROY LADURIE, "Peasants," in *The New Cambridge Modern History,* vol. 12, *Companion Volume,* edited by PETER BURKE (1979), pp. 115–163; and two valuable essay collections: JACK M. POTTER, MAY N. DIAZ, and GEORGE M. FOSTER (eds.), *Peasant Society* (1967); and TEODOR SHANIN (ed.), *Peasants and Peasant Societies* (1971, reprinted 1984). Peasantry in medieval Europe is described and analyzed by BARBARA A. HANAWALT, *The Ties That Bound: Peasant Families in Medieval England* (1986); and GEORGES DUBY, *Rural Economy and Country Life in the Medieval West* (1968, reprinted 1976; originally published in French, 2 vol., 1962).

Studies of peasantries have generated important theoretical arguments. Perhaps most notable is the "dual society" concept proposed by J.H. BOEKE, *Economics and Economic Policy of Dual Societies, as Exemplified by Indonesia* (1953, reprinted 1978). See also J.S. FURNIVALL, *Netherlands India: A Study of Plural Economy* (1939, reprinted 1983); and CLIFFORD GEERTZ, *Agricultural Involution: The Process of Ecological Change in Indonesia* (1963, reprinted 1968). With regard to Latin-American studies, ROBERT REDFIELD was an innovator in comparative field studies, introducing a conception of historical stages in *The Folk Culture of Yucatan* (1941, reprinted 1968). Other important analyses of Latin-American Indian peasantries are GEORGE M. FOSTER, *Tzintzuntzan: Mexican Peasants in a Changing World,* rev. ed. (1979); GEORGE MCCUTCHEN MCBRIDE, *Chile: Land and Society* (1936, reprinted 1971); and CHARLES WAGLEY, *The Latin American Tradition: Essays on the Unity and the Diversity of Latin American Culture* (1968). CONRAD M. ARENSBERG initiated anthropological study of Irish peasantry in *The Irish Countryman* (1937, reissued 1968). On Asia and the Far East, see HSIAO-TUNG FEI, *Peasant Life in China: A Field Study of Country Life in the Yangtze Valley* (1939, reprinted 1980); S.C. DUBE, *India's Changing Villages* (1958, reissued 1967); and THOMAS C. SMITH, *Agrarian Origins of Modern Japan* (1959, reissued 1966). See also DAVID BROKENSHA and MARION PEARSALL (eds.), *The Anthropology of Development in Sub-Saharan Africa* (1969); and GEORGE DALTON, *Economic Anthropology and Development: Essays on Tribal and Peasant Economies* (1970). On the rise of peasantry in relation to urban centres see WALTER GOLDSCHMIDT, *Man's Way: A Preface to the Understanding of Human Society* (1959, reprinted 1966). (E.R.Se./Ed.)

Overviews of the anthropological study of cities and urban cultures can be found in ULF HANNERZ, *Exploring the City* (1980); RICHARD G. FOX, *Urban Anthropology* (1977); and EDWIN EAMES and JUDITH GRANICH GOODE, *Anthropology of the City* (1977). Urban anthropological research papers are collected in GEORGE GMELCH and WALTER P. ZENNER (eds.), *Urban Life* (1980); THOMAS W. COLLINS (ed.), *Cities in a Larger Context* (1980); and IRWIN PRESS and M. ESTELLIE SMITH (eds.), *Urban Place and Process* (1980). The integration of micro-level and macro-level urban research is best seen in studies of industrial or mass-communications cities in advanced capitalist cultures, such as in MANUEL CASTELLS, *The Urban Question* (1977, reprinted 1979; originally published in French, 1972), and *The City and the Grassroots: A Cross-Cultural Theory of Urban Social Movements* (1983); DAVID HARVEY, *Consciousness and the Urban Experience* (1985), and *The Urbanization of Capital* (1985); MICHAEL PETER SMITH (ed.), *Cities in Transformation: Class, Capital and the State* (1984); WILLIAM K. TABB and LARRY SAWERS (eds.), *Marxism and the Metropolis,* 2nd ed. (1984); and DOLORES HAYDEN, *The Grand Domestic Revolution: A History of Feminist Designs for American Homes, Neighborhoods, and Cities* (1981, reprinted 1983). This theoretical integration is also to be found in studies of neocolonial cities and Third World urban culture, such as LARISSA ADLER LOMNITZ, *Networks and Marginality: Life in a Mexican Shantytown* (1977; originally published in Spanish, 1976); ALAN GILBERT and JOSEF GUGLER, *Cities, Poverty, and Development* (1982, reprinted 1984); BRYAN ROBERTS, *Cities of Peasants* (1978, reissued 1979); PETER LLOYD, *A Third World Proletariat?* (1982), and *Slums of Hope? Shanty Towns of the Third World* (1979); WAYNE A. CORNELIUS, *Politics and the Migrant Poor in Mexico City* (1975); OSCAR J. MARTÍNEZ, *Border Boom Town: Ciudad Juarez Since 1848* (1978); and JANICE E. PERLMAN, *The Myth of Marginality: Urban Poverty and Politics in Rio de Janeiro* (1976, reprinted 1979).

(R.G.F.)

Cyprus

The island of Cyprus (Greek: Kípros; Turkish: Kıbrıs) lies in the eastern Mediterranean, about 40 miles (64 kilometres) south of Turkey, about 60 miles (97 kilometres) west of Syria, and some 480 miles (772 kilometres) southeast of mainland Greece. Its maximum length, from Cape Arnauti in the west to Cape Apostolos Andreas at the end of the northeastern peninsula, is 140 miles; the maximum north–south extent is 60 miles. With an area of 3,572 square miles (9,251 square kilometres), it is the third largest Mediterranean island (after Sicily and Sardinia). The general pattern of its 486-mile coastline is indented and rocky, with long, sandy beaches.

Cyprus consists of two states, the Republic of Cyprus (Greek: Kipriakí Dimokratía; Turkish: Kıbrıs Cumhuriyeti), which occupies the southern two-thirds of the island, and the Turkish Republic of Northern Cyprus (Kuzey Kıbrıs Turk Cumhuriyeti), which since its declaration has been recognized only by Turkey. The capital for both states is Nicosia (Greek: Levkosía; Turkish: Lefkoşa).

The first human settlement was in the Neolithic Period. The immigration of settlers from Greece, which began about 1200 BC, led to the dominance of the Greek language and culture. Since then Cyprus has come under the influence or control of the various groups that have exercised power in the eastern Mediterranean—Phoenicians, Assyrians, Egyptians, Persians, the Greek monarchies of Alexander the Great and his successors, the Roman Empire from its successive capitals of Rome and Constantinople, French crusaders, Genoese, Venetians, and Ottomans.

The British occupied the island in 1878 and left in August 1960, when Cyprus became independent as the Republic of Cyprus. The long-standing conflict between the Greek-Cypriot majority and the Turkish-Cypriot minority intensified; in 1974 an invasion by Turkish troops produced an effective although unrecognized partition of the island and led to the declaration in 1975 of the separate Turkish-Cypriot state in the northern part. The Turkish-Cypriot state made a unilateral declaration of independence in 1983 and adopted its current name.

This article is divided into the following sections:

Physical and human geography

THE LAND

Relief. The saucepan shape of Cyprus results from its topography, which, in turn, reflects its geology. The 100-mile-long Kyrenia Mountains—the western portion of which is also known as the Pentadaktylos range for the five-fingered peak that is one of its main features—runs parallel to and just inland from the northern coast. It is the southernmost range of the great Alpine–Himalayan chain in the eastern Mediterranean; like much of that extensive mountain belt, it is formed largely of thrust masses of Mesozoic limestone.

Formation of the Troodos Mountains

The Troodos Mountains in the south and southwest are of great interest to geologists, who have concluded that the range, made up of igneous rock, was formed from molten rock beneath the deep ocean (Tethys) that once separated the continents of Eurasia and Afro-Arabia. The range stretches eastward about 50 miles from near the island's west coast to Stavrovouni peak (2,260 feet [689 metres]), about 12 miles from the southeast coast. The range's summit, Mt. Olympus (also called Mt. Troodos), the island's highest point, reaches an elevation of 6,401 feet (1,951 metres).

Between the two ranges lies the Mesaoria Plain (its name means "Between the Mountains"). The plain, which is flat and low-lying, extends from Morphou Bay in the west to Famagusta Bay in the east. Roughly in the centre of the plain is the capital, Nicosia. The plain is the principal cereal-growing area in the island. About half of its 727 square miles are irrigated; the remainder are devoted to dryland farming.

Drainage. All of the major rivers in Cyprus originate in the Troodos Mountains. The Pedieos, which is the largest, flows eastward toward Famagusta Bay; the Karyoti flows westward to Morphou Bay; and the Kouris flows southward to Episkopi Bay. The rivers depend on winter rainfall; in summer they become dry courses.

Climate. Cyprus has an intense Mediterranean climate with a typically strongly marked seasonal rhythm. Hot dry summers from June to September and rainy, rather changeable, winters from November to March are separated by short autumn and spring seasons of rapid change in October and in April and May. Autumn and winter rain, on which agriculture and water supply in general depend, is variable. Average annual rainfall is about 20 inches (500 millimetres). The lowest average precipitation is 14 inches at Nicosia and the highest 41 inches on Mt. Olympus. At Nicosia summer temperatures range between an average daily maximum of 98° F (37° C) and an average daily minimum of 70° F (21° C); in winter the range is between 59° F (15° C) and 41° F (5° C). From December to March the Troodos range experiences several weeks of below-freezing night temperatures.

MAP INDEX

Plant and animal life. There is a narrow fertile plain along the northern coast where the vegetation is largely evergreen but also includes olive, carob, and citrus trees. The Troodos range has a covering of pine, dwarf oak, cypress, and cedar forest. The southern and western slopes are extensively planted with vines. Between autumn and spring the Mesaoria Plain is green and colourful, with an abundance of wildflowers and flowering bushes and shrubs; there are also patches of woodland in which eucalyptus and many types of acacia, cypress, and lowland pine are found. At the island's western end in the area around Morphou there are orange plantations.

Fossil remains of elephant and hippopotamus have been found in the Kyrenia area, and in classical times there were large numbers of deer and boar, but the only large wild animal now surviving is the *agrino,* a species of wild sheep related to the mouflon of the western Mediterranean. It is under strict protection in a small forested area of the Troodos range. Small game is abundant but keenly hunted. Snakes, in classical times so ubiquitous as to earn the island the name of Ophiussa, "the Abode of Snakes," are now comparatively rare.

Migration route for birds

Cyprus lies on major migration routes for birds, and in spring and autumn many millions pass through. Many species also winter on the island. There are many resident species, including francolin and chukar partridges.

Settlement patterns. The Cypriots were traditionally a largely rural people, but a steady drift to the towns began early in the 20th century. The census of 1973 recorded six towns, defined as settlements of more than 5,000 inhabitants, and almost 600 villages. This pattern was altered after the Turkish invasion of 1974 by the need to resettle in the southern part of the island some 180,000 Greek-Cypriot refugees from the Turkish-occupied north. The accommodation built for them was situated mainly in the neighbourhood of the three towns south of the line of demarcation, and especially in the part of the Nicosia suburban area still controlled by the government of the Republic of Cyprus. In contrast, the northern portion of the island is now more thinly populated in spite of the influx of Turkish Cypriots transferred from the south and of immigrants from Turkey.

Cyprus' principal towns

The six towns recorded in the 1973 census, under the undivided republic, were the headquarters of the island's six administrative districts. Of these Kyrenia (Turkish Girne), Famagusta (Greek Ammókhostos, Turkish Mağusa), and the northern half of Nicosia are to the north of the demarcation line drawn in 1974 and are in Turkish-Cypriot hands.

Limassol, Larnaca, Paphos, and the southern part of Nicosia remained in Greek-Cypriot hands after 1974; the northern part of Nicosia became the administrative centre of the Turkish-Cypriot sector.

THE PEOPLE

Ethnic composition. The people of Cyprus represent two main ethnic groups, Greek and Turkish. The Greek Cypriots, who constitute the majority, are descended from a mixture of aboriginal inhabitants with immigrants from the Peloponnese who colonized Cyprus about 1100 BC and assimilated subsequent settlers up to the 16th century. The Turkish Cypriots are the descendants of the soldiers of the Ottoman army that conquered the island in 1571 and of immigrants from Anatolia brought in by the Sultan's government shortly thereafter. Since 1974 additional immigrants from Anatolia, with their families, have been brought in to work vacant land and increase the total labour force.

Linguistic composition. The language of the majority is Greek and of the minority Turkish. English is widely spoken and understood as a second language. Illiteracy is low, thanks to the excellence of the educational system.

Religions. The Greek Cypriots are Eastern Orthodox Christians. Their church, the Church of Cyprus, is autocephalous—*i.e.,* not under the authority of any patriarch; this privilege was granted to Archbishop Anthemius in AD 488 by the Byzantine emperor Zeno. Under the Ottoman Empire the archbishop of the Church of Cyprus was made responsible for the secular as well as the religious behaviour of the Orthodox community and given the title ethnarch. The Turkish Cypriots are Sunnī Muslims. There are also Maronites, Armenians, Roman Catholics, and Anglicans on the island.

Emigration of Cypriots

Demographic trends. Cypriots at times have emigrated in large numbers, and it is estimated that as many live abroad as on the island itself. The great majority of emigrants has always gone to the United Kingdom and the rest mainly to the English-speaking countries: Australia, South Africa, the United States, and Canada. Waves of heavy emigration followed the negotiation of independence in 1960 and the Turkish invasion in 1974. As a result of emigration and other factors, such as war losses and a temporary decline in fertility, the population decreased by about 5 percent between mid-1974 and 1977. The years since 1974 also have been marked by an increase in persons leaving the island in search of work, especially in the Middle East.

THE ECONOMY

The economy after independence. Between 1960 and 1973 the Republic of Cyprus, operating a free enterprise economy based on agriculture and trade, achieved a standard of living higher than most of its neighbours, with the exception of Israel. This progress was substantially assisted by various agencies of the United Nations, operating through the UN Development Program. Generous financial assistance was given by the World Bank and the International Monetary Fund in the form of loans for specific development projects (electricity supply, port development, and sewerage, among others). Aid was also made available by individual foreign countries. Experts were provided to advise on economic planning and to initiate productive projects, and training for Cypriot specialists was encouraged by scholarships and grants. During this period the gross domestic product grew at an average annual rate of over 7 percent, and per capita national income by about 6 percent annually. Agricultural production doubled; industrial production and exports of goods and services more than trebled. Tourism became the largest single earner of foreign exchange.

Foreign economic aid

Effects of partition. The Turkish occupation of 37 percent of the country in 1974, involving the displacement

Petra tou Romiou, the legendary site of Aphrodite's emergence from the sea, on the southwest coast of Cyprus near Old Paphos.

of about a third of the population, dealt a serious blow to economic development. Losses of land and personal property in the occupied areas were very great. The gross domestic product of the Greek-Cypriot sector dropped sharply, the reduction amounting to 33 percent (at constant 1973 prices) between 1973 and 1975. By vigorous efforts real growth was resumed in the area left under the control of the government of the Republic of Cyprus, and between 1975 and 1983 the annual rate of growth was estimated to average about 8 percent.

The Turkish-occupied area did not enjoy the same prosperity, and its economy was supported by subsidies from the Turkish government. Trade between the two areas ceased and the two economies became entirely independent, although the southern zone continued to supply the northern with certain services such as electricity and the northern zone supplied water to the south.

Copper

Resources. Cyprus was for many centuries a noted producer of copper; in Greek the name of the island and the name of the metal are identical. As early as 2500 BC its mines were being exploited, and traces of prehistoric and Roman workings and surface slags are still to be seen. With the discovery of other sources the mines remained neglected for many centuries until they were reopened shortly before World War I. They were exploited more seriously from 1925 until they were closed by the Great Depression of the 1930s. After World War II they were brought back into production, and since then copper and other minerals—iron pyrites, asbestos, gypsum, chrome ore—have contributed moderately to the export trade. Reserves of copper ore have declined but there are substantial reserves of asbestos, chrome, gypsum, and iron pyrites. There are also extensive quarries of good building stone. The island's most important copper mines are located in the area of Skouriotissa in the Turkish-occupied zone.

Agriculture, forestry, and fishing. Of the arable land on the island, about one-fourth is irrigated, mainly in the Mesaoria Plain and around Paphos in the southwest. Pastures occupy about 10 percent of the total land area. Landholdings are generally small, highly fragmented, and dispersed under traditional laws of inheritance. A program of land consolidation was enacted in 1969, but it met with resistance, particularly from Turkish-Cypriot landowners, and was only very slowly implemented.

The major crops of the Greek-Cypriot sector include grapes, deciduous fruits, vegetables, olives, and carobs. The area under Turkish occupation produces the bulk of the country's citrus fruits, wheat, barley, carrots, tobacco, and green fodder.

Livestock—especially sheep, goats, and pigs—and livestock products historically have accounted for about one-third of the island's total agricultural production. Some cattle are also raised.

Cyprus was once famous for its extensive forests, but the demand for timber for shipbuilding by successive conquerors from the 7th century BC onward, and extensive felling for building and for fuel, have destroyed the greater part. Under the British administration a vigorous policy of conservation and reforestation was pursued, and the Cyprus Forestry College was established at Prodhromos, on the western slopes of Mt. Olympus. Forests cover some 520 square miles, most of them being found in the mountain areas and in the Paphos district.

The fishing industry is small, in part because coastal waters are deficient in nutrients and associated plankton. Although the industry has shown some growth in the Greek-Cypriot sector, most fish is imported.

Manufacturing and tourism

Industry. Resources of raw materials on Cyprus are very limited, restricting the scope for industrial activity. Before the partition of the island most manufacturing was of goods produced for the domestic market by small, owner-operated plants, and a considerable number of those plants were located in the area that was occupied by the Turks in 1974. Industries in the Republic of Cyprus were subsequently reoriented toward production for export, and a number of larger factories were built in the south. Petroleum refining, cement and asbestos pipe production, and thermal electricity production are the republic's heavy industries, and its light industries produce goods such as clothing, footwear, and machinery and transport equipment.

Tourism became one of Cyprus' major industries after 1960. About 65 percent of tourist accommodation, however, was in the portion of the island that was occupied by the Turks in 1974. After partition the tourist trade recovered rapidly in the Greek-Cypriot sector: to counter the loss of Kyrenia and the Famagusta–Varosha area, which had been the leading seaside resorts, the southern coastal towns of Limassol, Larnaca, and Paphos were further developed to accommodate tourists.

Finance and trade. The Republic of Cyprus began to expand financial services, including offshore banking, in 1982. Light manufactures, particularly clothing and footwear, and foodstuffs, including potatoes and citrus fruit, constitute the Republic of Cyprus' major exports. Machinery and transport equipment, petroleum and petroleum products, and foodstuffs and live animals are imported. Chronic trade deficits are offset by receipts from tourists, remittances sent home by expatriate Greek Cypriots, and receipts from the British military bases on the island. In the Turkish sector, citrus fruits, potatoes, and carobs are the principal exports.

Transportation. In Roman times the island had a well-developed road system, but by the time of the British occupation in 1878 the only carriage road was between Nicosia and Larnaca. An extensive new road network was built under the British administration. A narrow-gauge public railway proved uneconomical and was closed in the early 1950s. Because there are no public railways, inland travel depends entirely upon roads, and motor transport has greatly increased.

International air services provide connections to all parts of Europe and the Middle East and to some points in Africa. Nicosia International Airport was closed in 1974, and the airport at Larnaca was developed in its stead. An airport at Paphos, opened in 1985, is also used for international flights. An airport at Geçitiikale (Lefkoniko) in the Turkish-occupied sector is used by flights coming from or through Turkey.

There is no coastal shipping, and much of the merchant marine registered to Cyprus is foreign-owned. The great bulk of the island's international trade remains seaborne, however, the main ports being Limassol and Larnaca; Turkish shipping uses Famagusta.

GOVERNMENT AND SOCIAL CONDITIONS

Government. The constitution of the Republic of Cyprus, adopted in 1960, provided that the executive power be exercised by a Greek-Cypriot president and a Turkish-Cypriot vice president, elected to five-year terms by universal suffrage, and that there be a Council of Ministers (Cabinet) comprising seven Greek-Cypriot and three Turkish-Cypriot members. There was also to be an elected House of Representatives with 50 seats, divided between Greek and Turkish Cypriots in the proportion of 35 to 15 and elected for five years.

Objections to the constitution of 1960

The constitution, derived from the negotiations in Zürich in 1959 between representatives of the governments of Greece and Turkey, did not inspire enthusiasm among the citizens of the new republic, however. The Greek Cypriots, whose struggle against the British had been for enosis (union with Greece) and not for independence (see below *History: British rule*), regretted the failure to achieve this national aspiration. As a result it was not long after the establishment of the republic before the Greek-Cypriot majority began to regard many of the provisions, particularly those relating to finance and to local government, as unworkable. Proposals for amendment were rejected by the Turkish government and, after the outbreak of fighting between the two Cypriot communities in late 1963, the constitution went largely into abeyance. In the territory controlled by the government of the Republic of Cyprus after the Turkish occupation of 1974, the constitution's provisions are considered as still in force where practicable; the main formal change has been the gradual increase of the number of seats in the House of Representatives, all of which are held by Greek Cypriots.

On the Turkish side of the demarcation line there have

been, since 1974, an elected president, prime minister, and legislative assembly, all serving five-year terms of office. A new constitution was approved for the Turkish Republic of Northern Cyprus by its electorate in 1985.

Local government. Local government in the Republic of Cyprus is at the district, municipal, rural municipality, and village level. District officers are appointed by the government; local councils are elected, as are the mayors of municipalities.

Justice. The legal code of Cyprus is based on Roman law. In the Greek-Cypriot zone judges are appointed by the government, but the judiciary is entirely independent of the executive power. There are a supreme court and an appeals court, district assize courts handling criminal matters, and district courts exercising summary jurisdiction. The Turkish-Cypriot zone has a similar system of justice.

Political parties. The oldest established political party in the Republic of Cyprus is the Anorthotiko Komma Ergazomenou Laou (AKEL; Progressive Party of the Working People), founded in 1941. It is a pro-Moscow Communist party, and it controls the principal trade union federation; its share of the vote in the first 25 years of the Republic of Cyprus was usually in the neighbourhood of 30 percent. Other parties have had varying success. Among them are the Eniea Demokratiki Enosis Kyprou (Cyprus National Democratic Union), a Socialist party; the Enosi Kentrou (Centre Union); the Demokratikos Synagermos (Democratic Rally); and the Demokratiko Komma (Democratic Party). In the Turkish-Cypriot zone the major parties are the Ulusal Birlik Partisi (National Unity Party) and the Toplumcu Kurtuluş Partisi (Communal Liberation Party).

Compulsory elementary education

Education. Six grades of free and compulsory elementary education are provided for children beginning at age five. At least three years of the five-year secondary education program are free, and all secondary education at technical schools is free. Post-secondary facilities include schools for teacher training, technical instruction, hotel and catering training, nursing, and midwifery. The education system in the Turkish sector is administered separately. Cyprus has no university, but many students attend universities abroad, especially in Greece, Turkey, Britain, or the United States.

Health. Health standards are high because of a favourable climate and well-organized public and private health services. Since the eradication of malaria shortly after World War II and, later, of echinococcosis (hydatid disease), the island has been free from major diseases.

Cultural life. The very ancient cultural traditions of Cyprus are maintained partly by private enterprise and partly by government activity, especially on the part of the Cultural Service of the Republic of Cyprus' Ministry of Education. The Cultural Service publishes books and awards prizes for literature. Mobile libraries operate in rural areas. The government-sponsored Cyprus Theatrical Organization stages plays by contemporary Cypriot dramatists as well as classical works. The ancient theatres of Salamis, Curium, and Soli have been restored and are used for the staging of a variety of plays, and a Greek theatre has been built at Nicosia.

Literature, theatre, and art

Many painters and sculptors work in Cyprus, and the Cultural Service keeps the state's collection of modern Cypriot art on permanent exhibition. In the village of Lemba near Paphos the Cyprus College of Art runs courses for postgraduate art students. Government encouragement is given to young composers.

Television and radio are controlled by the semigovernmental Cyprus Broadcasting Corporation and are financed by advertising. The Turkish sector receives broadcasts from Turkey. Languages used are Greek, Turkish, English, and Armenian. Many daily and weekly newspapers are published in Greek, Turkish, and English.

For statistical data on the land and people of Cyprus, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR. (H.W.G./D.W.S.H.)

History

The earliest evidence of human habitation in Cyprus comes from the Neolithic Period. The settlement at Khirokitia (near the southern coast), which is now dated to well before 6000 BC, is one of the most remarkable Neolithic communities ever excavated in Europe. It was a town of about 2,000 inhabitants, living in well-built round stone houses of two stories. The Khirokitians made little use of pottery, using stone, and presumably wood, for utensils and stone for tools. The presence of flakes of obsidian, which is not native to the nonvolcanic island of Cyprus, is the only sign of contact with other cultures. Khirokitia and a few smaller associated settlements appear to have died out after a few centuries, leaving the island uninhabited again for some 2,000 years. The beginning of the next period of habitation, known as the Sotira culture, is dated to between 4500 and 4000 BC; small villages of this culture are found not only at Sotira (near the southern coast, north of Curium) but also in the Kyrenia range. Small ornaments of picrolite (a variety of soapstone) and a progressively more attractive pottery distinguish the Sotira culture; toward the end of the period copper came into use.

Khirokitia and Sotira settlements

BRONZE AGES

After the Chalcolithic Age, dating from 3000 to 2500 BC, began the Bronze Ages, which in Cypriot archaeology are treated as separate from the Chalcolithic and which lasted for about 1,500 years. The Middle Bronze Age (1900–1600 BC) produced several styles of well-made and competently decorated pottery, and its bronze implements show a well-advanced craftsmanship; imports from Crete, Anatolia, Syria, and Egypt prove that external trade had begun. It has been conjectured that the name Alashiya or Alasia, which occurs in Hittite and Egyptian records in connection with the supply of copper, refers to Cyprus. These trade links probably account for the foundation of the new settlements in the east of the island that were to develop into international urban emporiums.

The Late Bronze Age (1600–1050 BC) was one of the most formative periods of the life of ancient Cyprus. The island's international contacts extended from the Aegean Sea to the Levant and the Nile Delta. (Thutmose III of Egypt claimed Cyprus as one of his conquests in about 1500 BC.) Writing, in the form of a linear script known as Cypro-Minoan, was borrowed from Crete. Cypriot craftsmen were distinguished for fine jewelry, ivory carving, and bronze figures. From about 1400 BC a profusion of Mycenaean pottery was imported from mainland Greece, and it is possible that Mycenaean artists accompanied the merchants. After 1200 BC, with the collapse of Mycenaean civilization, there is evidence of Greek immigration from the Peloponnese. The principal city, and port, was Engomi (west of Famagusta); its massive city walls and houses of hewn stone are evidence of a high degree of prosperity.

GREEK IMMIGRATION

Immigration from the Peloponnese

The mass immigration of Greek-speaking peoples from the Peloponnese began with the Iron Age (1100–700 BC). From the start of the 1st millennium the Greek language has been dominant in Cyprus; the fact that the dialectal form in which it first appears is known as Arcado-Cypriot confirms traditions of the Peloponnesian origin—and specifically of the Arcadian origin—of the immigrants. They founded new cities, which became the capitals of six ancient Greek kingdoms on Cyprus: Curium (Greek Kourion), Paphos, Marion, Soli (Greek Soloi), Lapithos, and Salamis. In about 800 BC a Phoenician colony was founded at Citium (Greek Kition), near modern Larnaca. The colony was a dependency of the mother city, Tyre. A seventh kingdom, that of Amathus, remained for some time under the control of the earlier indigenous inhabitants; the language used there was called Eteo-Cypriot ("True Cypriot") by the Greeks. Amathus was active politically, especially in external trade relations. The later Iron Age was a period of advancing civilization, as evidenced by the spectacular chariot-burials of the royal family of Salamis, which so closely match descriptions in the Homeric poems as to suggest inspiration by them.

EXTERNAL POLITICAL INFLUENCES

Assyrian and Egyptian domination. In 709 BC Sargon II of Assyria erected a stela at Citium recording the fact that

seven Cypriot kings had paid him homage; subsequent Assyrian documents speak of 11 tributary kingdoms, the seven already mentioned plus Citium, Kyrenia, Tamassos, and Idalium. This subordination to Assyria, probably rather nominal, lasted until about 663 BC. For the next hundred years Cyprus enjoyed a period of complete independence and exuberant development. Epic poetry was greatly popular, as it had always been, and much was written on the island; Stasinus of Cyprus, credited with the authorship of the lost epic poem *Cypria,* was reckoned among the most important poets in this style in the 7th century. Bronze work and ironwork, a spirited style of ceramic decoration, and delicate jewelry and ivory work are characteristic of this period; among outstanding works are the sumptuous ivory throne and bedstead excavated from a royal tomb at Salamis dated from about 700 BC.

Egyptian dominance

When the Assyrian Empire finally broke up at the end of the 7th century BC, Egypt, under the Saite dynasty, became the predominant power in the eastern Mediterranean. In about 569 BC the Cypriot kingdoms recognized the pharaoh Ahmose II as their overlord. Direct Egyptian influence was not always apparent, although many limestone sculptures reproduce Egyptian conventions in dress and some statues are directly inspired by Egyptian models. A more important influence in the last years of the Archaic period (750–475 BC) came from the artistic schools of Ionia. From the same source probably came the inspiration for the issue of coinage; the first Cypriot coins were struck for Euelthon, king of Salamis (560–525 BC).

The Persian Empire. In 525 BC the Cypriot kings transferred their allegiance to the Achaemenid (Persian) conquerors of Egypt. The Cypriots retained their independence until the accession of Darius I (522 BC) but were then incorporated into the fifth satrapy of the Persian Empire. When the Ionians revolted in 499 BC all the kingdoms of Cyprus except Amathus joined them; the revolt was suppressed in about a year's campaigning, culminating in sieges of Paphos and Soli. In Xerxes I's invasion of Greece in 480 BC the Cypriot kings, like the Ionians, contributed naval contingents to his forces. During the 5th century Cyprus remained under Persian rule in spite of a major Athenian expedition there in 450/449 BC. Evagoras, who became king of Salamis in 411 BC, maintained a pro-Hellenic policy, with some help from Athens, and succeeded in extending his rule over a large part of the island. He was defeated by the Persians in 381 BC and was assassinated in 374 BC. After the victory of Alexander the Great over the last Achaemenid ruler, Darius III, at Issus in 333 BC, the Cypriot kings rallied to Alexander and assisted him at the siege of Tyre. During the period from 475 to 325 BC, known conventionally as the Classical Period, Cypriot art came under strong Attic influence.

Rule of the Ptolemies

Hellenistic and Roman rule. Alexander allowed the Cypriot kingdoms to continue but took from them the right of coinage. After his death in 323 BC Cyprus was contested by his successors; the eventual victor was Ptolemy I of Egypt, who suppressed the kingdoms and made the island a province of his Egyptian kingdom. He forced the last king of Salamis, Nicocreon, to commit suicide in 310 BC, together with all his family; their cenotaph, a particularly fine specimen containing ornaments and clay effigies of the royal families, has been discovered. For two and a half centuries Cyprus remained a Ptolemaic possession, ruled by a strategus, or governor-general.

Cyprus as a Roman province. Cyprus was annexed by the Roman Republic in 58 BC and, along with Cilicia on the coast of Anatolia, was made into a Roman province. The orator and writer Cicero was one of its first proconsuls. Cyprus was briefly retroceded to Cleopatra VII of Egypt by Julius Caesar, and this status was confirmed by Mark Antony, but after the victory of Caesar's heir, Octavian (subsequently the emperor Augustus), over Mark Antony and Cleopatra at Actium in 31 BC it became a Roman possession again. It was originally administered as part of the "imperial" province of Syria but became a separate "senatorial" province in 22 BC in consequence of the constitutional settlement of the previous year. Its governors resumed the old republican title of proconsul, although there is evidence that Augustus could, and on one occasion did, influence the Senate's choice. For the next 600 years Cyprus enjoyed a profound peace, disturbed only by occasional earthquakes and epidemics and by a Jewish uprising put down by a lieutenant of the future emperor Hadrian in AD 116. Many large public buildings were erected: among them were a gymnasium and theatre at Salamis, a theatre at Curium, and the governor's palace at Paphos.

Introduction of Christianity

Early Christianity. Undoubtedly the most important event in the Roman period was the introduction of Christianity. The Apostle Paul, accompanied by Barnabas (later St. Barnabas), a native of the Cypriot Jewish community, preached there in about AD 45 and converted the proconsul, Sergius Paulus. By the time of Constantine I the Great, Christians were numerous in the island and may have constituted a majority.

Byzantine Empire. After the division of the Roman Empire (AD 395) Cyprus remained subject to the Eastern, or Byzantine, Empire at Constantinople, being part of the Diocese of the Orient governed from Antioch. In ecclesiastical matters, however, the Church of Cyprus was autocephalous—*i.e.,* independent of the Patriarchate of Antioch—having been given that privilege in 488 by the emperor Zeno. The archbishop received the rights, still valued and practiced, of carrying a sceptre instead of a crozier and writing his signature in ink of imperial purple.

There was a break in direct rule from Constantinople in 688 when Justinian II and the caliph ʿAbd al-Malik signed an unusual form of treaty neutralizing the island, which had been subject to Arab raids. For almost 300 years Cyprus was a kind of condominium of the Byzantine Empire and the Caliphate, and although the treaty was frequently violated by both sides, the arrangement lasted until 965, when the emperor Nicephorus II Phocas gained Cyprus completely for the Byzantines.

This appears to have been a period of modest prosperity. A remarkable mosaic of the 6th century, at Kiti, is the best example of Eastern Roman art of that date, comparable with works at Ravenna in Italy. Another equally remarkable mosaic of roughly the same date, at Lythrangomi, was destroyed in 1974. Wall paintings demonstrate close contact with Constantinople: those at Asinou, in particular, are noteworthy as being the earliest of an unparalleled series of mural paintings showing successive developments of Byzantine art.

In about 1185 a Byzantine governor of Cyprus, Isaac Comnenus, rebelled and proclaimed himself emperor. Isaac resisted attacks from the Byzantine emperors Andronicus I Comnenus and Isaac II Angelus, but in 1191, on engaging in hostilities with an English crusader fleet under King Richard I the Lion-Heart, he was defeated and imprisoned. The island was seized by Richard, from whom it was acquired by the crusading order of the Knights Templar; because they were unable to pay his price he took it back and sold it to Guy of Lusignan, the dispossessed king of Jerusalem.

The Lusignan kingdom, Genoese rule, and Venetian rule. Guy, who called himself lord of Cyprus, invited families that had lost their lands in Palestine after the fall of Jerusalem to take up land in Cyprus. He thereby laid the basis for a feudal monarchy that survived to the end of the Middle Ages. His brother and successor, Amalric, obtained the title of king from the Holy Roman emperor Henry VI. The earliest kings of the Lusignan dynasty were involved in the affairs of the small territory still left to the Kingdom of Jerusalem, and this commitment caused a heavy drain on the resources of Cyprus until the kingdom was extinguished in 1291 with the fall of Acre. Over the next hundred years Cyprus enjoyed a reputation in Europe for immense riches where its nobles and merchants (especially Famagusta merchants) were concerned. Famagusta's opulence derived from its position as the last entrepôt for European trade adjacent to the Levant.

The kings of Cyprus had kept alive the crusading idea, and the island remained a base for counterattack against the Muslims. In 1361 the Cypriot king Peter I (reigned 1359–69) devoted himself to the organization of a crusade. He captured Adalia (Antalya) on the Cilician coast of Anatolia, and in 1365, after collecting money and mer-

cenaries in western Europe, seized and sacked Alexandria. He was not able to maintain the conquest, however, and was soon forced to abandon Alexandria. At his son's accession rivalry between Genoa and Venice, vying for control of Cyprus' valuable trade, resulted in Genoa's seizing Famagusta and holding it for almost a hundred years. This led to a rapid decline in the island's prosperity. In 1426 a marauding expedition from Egypt overran the island, which from then on paid tribute to Cairo. The last Lusignan king, James II (reigned 1460–73), a bastard of the royal house, seized the throne with the help of an Egyptian force and in 1464 expelled the Genoese from Famagusta. He married a Venetian noblewoman, Caterina Cornaro. On his death, which was followed by that of his posthumous son, she succeeded him as the last queen of Cyprus (1474–89). During her reign she was under strong Venetian pressure and was eventually persuaded to cede Cyprus to the Venetian Republic. It remained a Venetian possession for 82 years until its capture by the Ottomans.

Rivalry for control of Cyprus' trade

Many noteworthy buildings survive from the Lusignan and Venetian periods, in particular the Gothic cathedrals at Nicosia and Famagusta and the Abbey of Bellapais near Kyrenia. There are other Gothic churches throughout the island. Orthodox Christians also built numerous churches in a distinctive style, one often influenced by the Gothic, and the interiors illustrate the continued development of Byzantine art. Cyprus also has imposing examples of medieval and Renaissance military architecture, such as the castles of Kyrenia, St. Hilarion, Buffavento, and Kantara and the elaborate Venetian fortifications of Nicosia and Famagusta.

Ottoman rule. A Turkish invading force landed in Cyprus in 1570 and captured Nicosia; the following year Famagusta fell after a long siege. Ottoman rule lasted more than three centuries. The Latin church was suppressed and the Orthodox hierarchy restored; with the abolition of feudal tenure the Greek peasantry acquired inalienable and hereditary rights to land. Taxes were at first reduced but very soon were greatly increased and arbitrarily levied. In the 18th century the Orthodox archbishop was made responsible for tax collection.

About 20,000 Muslims (including the garrison, nominally 3,666 strong) were settled in the island in the immediate aftermath of the Ottoman conquest. Cyprus was an unimportant province to the sultans; its governors were slothful, inefficient, occasionally oppressive, and always venal. There were Turkish uprisings in 1764 and 1833; in 1821 the Orthodox archbishop was hanged on suspicion of sympathy with the rebellion in mainland Greece. The sultanate's various imperial proclamations in the 19th century promising reform had no effect in Cyprus, where local opposition prevented their application.

British rule. The Cyprus Convention of 1878 between Britain and Turkey provided that Cyprus, while remaining under Turkish sovereignty, should be administered by the British government. Britain's aim in occupying Cyprus was to secure a base in the eastern Mediterranean for possible operations in the Caucasus or Mesopotamia as part of the British guarantee to preserve the Sultan's Asian possessions from threat by Russia. In 1914, however, Britain and Turkey being at war, the former proclaimed the island annexed; Turkish recognition was granted under the Treaty of Lausanne (1923), and the position was regularized in 1925 when Cyprus was declared a crown colony.

British occupation was initially welcomed by the Greek population, who from the start expected the British to transfer Cyprus to Greece. The Greek Cypriots' demand for enosis (union with Greece) and a corresponding hostility to it on the part of Turkish Cypriots constituted almost the sole division in politics; almost annual petitions demanding enosis were matched by counter-petitions and demonstrations from the Turkish Cypriots. An offer to transfer the island had been made in 1915, on condition that Greece fulfill its treaty obligations toward Serbia when attacked by Bulgaria. The Greek government refused and the offer was not renewed. In 1931 the demand for enosis led to riots in Nicosia.

Demands for union with Greece

Cyprus was untouched by World War II apart from a few air raids. In 1947 the governor, in accordance with the British Labour Party's declaration on colonial policy, published proposals for greater self-government. They were rejected in favour of the slogan "enosis and only enosis." In 1955 Lieut. Col. Georgios Grivas (known as Dighenis), a Cypriot who had served as an officer in the Greek Army, began a concerted campaign for enosis. His National Organization of Cypriot Struggle (Ethnikí Orgánosis Kipriakoú Agónos; EOKA) bombed public buildings and attacked and killed opponents of enosis, both Greek-Cypriot and British. Proposals for self-government were put forward at different times; the most advanced were those of the British jurist Lord Radcliffe in 1956. All were rejected and the attacks continued. In March 1956 the archbishop, Makarios III, who as ethnarch considered it his duty to champion the national aspirations of the Greek Cypriots, was deported to the Seychelles. He was released from exile in March 1957 and left the Seychelles in April, but, being forbidden to return to Cyprus, he made his headquarters in Athens. By this time the operations of EOKA were much reduced, but on the other hand the Turkish-Cypriot minority, led by Fazıl Küçük, began to express alarm and demanded either retrocession to Turkey or partition. Public opinion in Greece and Turkey was much aroused in support of the two communities, resulting in riots and expulsions of Greek residents in Turkey. Frequent recourse to the United Nations produced no agreed solution.

The decisive step was taken by the Greek and Turkish governments, which in February 1959 reached agreement between themselves in Zürich. Later the same month, at a conference in London, the Greek–Turkish compromise was accepted by the British government and by representatives of the Greek-Cypriot and Turkish-Cypriot communities, led by Makarios and Küçük, respectively. In 1960 it was ratified by treaties agreed to in Nicosia. Cyprus became an independent republic, with Britain retaining sovereignty over the two military bases at Akrotiri and Dhekélia. According to the terms of the treaties, the new republic would not participate in a political or economic union with any other state, nor would it be subject to partition. Greece, Turkey, and Britain guaranteed the independence, integrity, and security of the republic, and Greece and Turkey undertook to respect the integrity of the areas remaining under British sovereignty. Makarios became president and Küçük vice president in elections held in December 1959. Decisions of the council of ministers would be binding on the president and vice president, either of whom could, however, exercise a veto in matters relating to security, defense, and foreign affairs. Turkish Cypriots, who made up less than 20 percent of the population, were to represent 30 percent of the civil service and 40 percent of the army and to elect one-third of the House of Representatives. A joint Greek and Turkish military headquarters was to be established.

Negotiations for independence

THE REPUBLIC OF CYPRUS

The first general election took place on July 31, 1960. Of the 35 seats allotted to the Greek Cypriots, 30 were won by supporters of Makarios, 5 by agreement being allotted to the Communist-led Progressive Party of the Working People (AKEL). All 15 Turkish-Cypriot seats were won by supporters of Küçük. The republic came into being on Aug. 16, 1960, and Cyprus was admitted as a member of the United Nations. The British government agreed to pay £12,000,000 in financial assistance over five years. Cyprus was admitted to membership in the Commonwealth in March 1961.

The difficulties experienced in implementing some of the complicated provisions of the constitution, particularly over local government and finance, led Makarios late in 1963 to propose to Küçük 13 amendments. These were rejected by the Turkish government and the Turkish Cypriots, and in the next month fighting broke out between the two Cypriot communities. As a result, the area controlled by the Turkish Cypriots was reduced to a few enclaves, and Nicosia was divided by a cease-fire line, policed to begin with by British troops. In March 1964 the UN Security Council agreed to send to Cyprus a multinational force known as the United Nations Peace-Keeping Force in Cyprus, or UNFICYP. Its mandate was

Conflict between Greek Cypriots and Turkish Cypriots

extended repeatedly in the course of the continuing conflict. In 1964 intensified fighting in the northwest caused the Turkish air force to intervene; at the same time a full-scale invasion was threatened. Contingents of troops from Greece and Turkey were brought into the island clandestinely together with officers to command and train the forces raised by the two communities. Grivas, who had been promoted to lieutenant general in the Greek army, returned from Greece to command the Greek-Cypriot National Guard. In 1967 an incident in the southeast led to a Turkish ultimatum to Greece, backed by the threat of invasion. The military junta then ruling Greece complied by withdrawing the mainland contingents together with General Grivas. An uneasy peace was established, but intercommunal talks failed to produce a solution.

Makarios was reelected president in 1968 by an overwhelming majority, and in 1973 his reelection was not even contested. Although Makarios had originally been a leader in the campaign for enosis, he was thought by many Greek Cypriots and mainland Greeks to be content with Cyprus's independence after he became president. Dissidents angered by that perception are assumed to have tried to assassinate him in 1970 and 1973. In 1973 Makarios was denounced by the three suffragan bishops ecclesiastically subordinate to him; they demanded that he renounce the presidency because it was in conflict with his role as a spiritual leader. Makarios circumvented them, however, by calling a synod of the Eastern Orthodox churches presided over by the patriarch of Alexandria. Meanwhile Grivas had returned secretly to Cyprus in 1971 to resume the campaign for enosis under a newly formed EOKA-B; he died in Limassol in 1974, at age 75. (D.W.S.H.)

Establishment of an independent Turkish state. On July 15, 1974, a detachment of the National Guard, led by officers from mainland Greece, launched a coup to assassinate Makarios and establish enosis. They demolished the presidential palace, but Makarios escaped. A former EOKA member, Nikos Sampson, was proclaimed president of Cyprus. Five days later Turkish forces landed at Kyrenia to overthrow Sampson's government. They were met by vigorous resistance, but the Turks were successful in establishing a bridgehead around Kyrenia and linking it with the Turkish sector of Nicosia. On July 23 Greece's junta fell and a democratic government under Konstantinos Karamanlis took power. At the same time, Sampson was replaced in Cyprus by Glafcos Clerides, who as president of the House of Representatives automatically succeeded the head of state in the latter's absence. The three guarantor powers—Britain, Greece, and Turkey—as required by the treaty, met for discussions in Geneva, but the Turkish advance continued until mid-August. By that time Turkey controlled roughly the northern third of the island. In December Makarios returned and resumed the presidency, and a few months later Turkish leaders proclaimed a Turkish Federated State of Cyprus under Rauf Denktash as president.

Proclamation of the Turkish Federated State of Cyprus

In May 1983 Denktash broke off all intercommunal talks, and in November he proclaimed the Turkish Republic of Northern Cyprus (TRNC); the republic's independence was recognized only by Turkey. The UN Security Council condemned the move and repeated its demand, first made in 1974, for the withdrawal of all foreign troops from the Republic of Cyprus. Renewed UN peace-proposal efforts in 1984 and 1985 were unsuccessful, and in May 1985 a constitution for the TRNC was approved by referendum.

The failure of intercommunal talks. Talks between Clerides and Denktash, representing the Greek and Turkish Cypriots, respectively, had begun in 1968. They continued inconclusively until 1974, the Turks demanding and the Greeks rejecting the proposal for a bizonal federation with a weak central government. In February 1975, after the Turkish Cypriots had proclaimed their own state in the Turkish-occupied area (a body calling itself the Provisional Cyprus-Turkish Administration had been in existence among Turkish Cypriots since 1967), Denktash claimed that their purpose was not independence but federation. Talks were resumed in Vienna in 1975 and 1976 under UN auspices, and in early 1977 Makarios and Denktash agreed on acceptable guidelines for a bizonal federation. In August Makarios died, and Spyros Kyprianou, president of the House of Representatives, became acting president of the republic. He returned unopposed to that office for a five-year term in January 1978 and was reelected in 1983; Turkish Cypriots took no part in the 1983 election. (D.W.S.H./J.S.Bo.)

Kyprianou lost his bid for a third term in 1988 to an independent candidate, Georghios Vassiliou, who won in the second round by a narrow margin. Vassiliou, in turn, lost by a narrow margin in 1993 to the rightist Glafcos Clerides, who was reelected in 1998. At first Clerides showed no willingness to deal with the Turkish-Cypriot leader Denktash, but the two eventually met in New York under UN auspices. In late 2002 the European Union offered Cyprus membership in its organization on the condition that reunification talks were concluded. Barring reunification, membership would go to the Greek Cypriot portion of the country only. In February 2003 Tassos Papadopoulos defeated Clerides and assumed the presidency of the Republic of Cyprus, but one month later reunification talks stalled. TRNC leaders responded by opening the border for the first time in some 30 years. The failure of a reunification vote in early 2004 was followed by further relaxing of border restrictions. (Ed.)

Czech and Slovak Republics

The modern states of the Czech Republic and Slovakia came into being on Jan. 1, 1993, with the dissolution of the Czechoslovak federation. Czechoslovakia itself had been formed in 1918 at the end of World War I, following the collapse of the Austro-Hungarian empire. Prior to that, the region consisted of three historical lands: Bohemia and Moravia in the west (often called the Czech Lands) and Slovakia in the east, which before World War I was a part of Hungary inhabited primarily by Slovaks. This region lay across the great ancient trade routes of Europe, and, by virtue of its position at the heart of the continent, it was one in which the most varied of traditions and influences encountered each other. The Czechs and Slovaks traditionally shared many cultural and linguistic affinities, but they nonetheless developed distinct national identities. The emergence of separatist tendencies in the early 1990s following the loosening of Soviet hegemony over eastern Europe led, by the end of 1992, to the breakup of the federation.

This article first discusses the history of the Czechoslovak region up to the dissolution of the federation. This is followed by treatments of the geography and recent history of the two republics.

The article is divided into the following sections:

HISTORY

The historical regions to 1914

The part of Europe that constitutes the modern states of the Czech Republic and Slovakia was settled first by Celtic, then by Germanic, and finally by Slavic tribes over the course of several hundred years. The major political and historical regions that emerged in the area are Bohemia, Moravia, and Slovakia. These regions coexisted, with a constantly changing degree of political interdependence, for more than a millennium before combining to form the modern state of Czechoslovakia in 1918. Each was subject to conquest, each underwent frequent shifts of population and periodic religious upheavals, and at times at least two of the three were governed by rival rulers. Bohemia and Moravia—the constituent regions of the Czech Republic—maintained close cultural and political ties and in fact were governed jointly during much of their history. Slovakia, however, which bordered on the Little Alfold (Little Hungarian Plain), was ruled by Hungary for almost 1,000 years and was known as Upper Hungary for much of the period before 1918. Thus, the division of Czechoslovakia in 1993 was based on long-standing historical differences.

ORIGINS AND EARLY HISTORY

Bohemia. The prehistoric people north of the middle Danube River were of uncertain origin. The Boii, a Celtic people, left distinct marks of a fairly long stay, but its time cannot be firmly established. The name Bohemia is derived through Latin from Celtic origins. The Celtic population was supplanted by Germanic tribes. One of them, the Marcomanni, inhabited Bohemia, while others settled in adjacent territories. No outstanding event marked the Marcomanni departure.

Movements of ethnic groups

Archaeological discoveries and incidental references to Bohemia in written sources indicate that the movements of ethnic groups were not always abrupt and turbulent but that the new settlers began to enter the territory before the earlier inhabitants had left it. It can be assumed, therefore, that the Slavic people were coming in groups before the southward migration of the Germanic tribes. In the 6th century AD, Bohemia and the neighbouring territories were inhabited by the Slavs.

While mountains and forests offered protection to Bohemia, the tribes in the lowlands north of the Danube and along its tributaries were hard-pressed by the Avars of the Hungarian plains. Attempts to unite the Slavic tribes against the Avars were successful only when directed by such personalities as the Frankish merchant Samo, who gained control of a large territory in which at least part of Bohemia was included. His death in 658 ended the loosely knit state. A more auspicious era dawned after Charlemagne defeated the Avars in the 8th century.

There followed a period of comparative security, in which the concentration of the Slavs into political organizations advanced more promisingly. Soon after 800 three areas emerged as potential centres: the lowlands along the Nitra River, the territory on both sides of the lower Morava (German: March) River, and central Bohemia, inhabited by the Czech tribe. In time, the Czechs, protected from foreign intruders, rose to a dominant position. Governed by rulers claiming descent from the legendary plowman Přemysl and his consort Libuše, the Czechs brought much of Bohemia under their control before 800 but failed to defeat the tribes in the east and northeast. Apart from occasional disturbances, such as Charlemagne's invasions (805), the Czech domain was not exposed to war and devastation, and little of the life there came to the notice of clerics who were recording contemporary events in central Europe. (O.O.)

Unification of Great Moravia. The earliest known inhabitants of Moravia were the Boii and the Cotini, another Celtic tribe. These were succeeded about 15–10 BC by the Germanic Quadi. The Germanic peoples were pushed back from the middle Danube by the coming of the Avars in AD 567. The exact date of the arrival of the Slavs in Moravia, as in Bohemia, is uncertain; but by the late 8th century Moravia was settled by the Slavs, who acknowledged no particular tribe but took the general

name of Moravians from the Morava River. An important trade route from the Baltic to the Adriatic Sea developed through the Morava River basin.

When Charlemagne destroyed the Avar empire about 796, he rewarded the Moravians for their help by giving them a part of it, which they held as a fief from him. They thus became loosely tributary to him for all their lands, but their princes enjoyed independence and often made war on him and on his successors, Louis I the Pious and Louis the German. By the first half of the 9th century, Moravia had become a united kingdom under Prince Mojmír I (ruled *c.* 818–*c.* 846).

In about 833 Mojmír attached the Nitra region (the western part of modern Slovakia) to his domain. His successor (after 846), Rostislav, consolidated the country and defended it successfully. His relations with the East Frankish empire (since 843 under Louis the German) were determined by political considerations and by the advance of Christianity into the Slavic areas. The bishoprics of Regensburg, Passau, and Salzburg competed in trying to convert the central European Slavs but achieved only limited success. The archbishop of Salzburg consecrated a church at Nitra about 828. In 845 Regensburg baptized 14 chieftains from Bohemia. Mojmír's Moravia apparently had more frequent contacts with Passau than with Salzburg. Archaeological discoveries in the 20th century indicate that missionaries made noticeable progress before 860; stone churches were built as places of Christian worship at Mikulčice and elsewhere.

Competition of bishoprics

But Rostislav was dissatisfied with the Latin-speaking Frankish clergy and asked the Byzantine emperor Michael III for Slavic-speaking preachers. A group of clerics headed by two brothers of Greek origin, Constantine and Methodius, arrived from Constantinople in 863. They not only preached in Slavic but also translated the sacred books into that language and used them in divine services. To Constantine is attributed the creation of the first Slavic alphabet. After some two and a half years, the two brothers journeyed to Rome to ask for papal support for their work and their use of the Slavic language. Constantine entered a convent in Rome, taking the name of Cyril; he died in 869. Methodius received the pope's sanction for his work in Moravia and in Pannonia, Moravia's southern neighbour. The two territories were organized as a province and connected with the ancient archbishopric of Sirmium, restored by the pope. Methodius' elevation to archbishop angered the Frankish clergy, who regarded his archdiocese as their missionary field. He was captured and imprisoned until 873; he then returned to Moravia and put himself under the protection of Rostislav's successor, Svatopluk. Relations between the ruler and the archbishop, however, were not harmonious. After Svatopluk's conciliation with the Franks at Forchheim (874), clerics of the Latin rite appeared again in Moravia, interfering with the archbishop's work. In 880 Methodius obtained from Pope John VIII a formal sanction of his work, including the Slavic liturgy.

Svatopluk distinguished himself in the conduct of political affairs. After the death of Louis the German (876), he acquired large territories with Slavic populations. The Great Moravia that he created included all of Bohemia, the southern part of modern Poland, and the western part of modern Hungary. He annexed some territories and left local princes who recognized his suzerainty in others. Such was apparently the case of the Czech prince Bořivoj I.

Political expansion

Propagation of Christianity followed Svatopluk's advances. According to legends, Bořivoj was baptized by Methodius and then admitted clerics of the Slavic rite to his principality. While the archbishop was engaged in missionary work in the annexed territories, however, advocates of the Latin rite, headed by a Frankish cleric, Wiching, bishop of Nitra, strengthened their position in Moravia. During Methodius' lifetime the Slavic clergy had the upper hand; but after his death (885) Wiching banned Methodius' disciples from Moravia, and most of them moved to Bulgaria. Pope Stephen V reversed his predecessor's policy and forbade the Slavic liturgy.

Svatopluk continued his policy of expansion for several more years, but soon after 890 he made the East Frankish king Arnulf his enemy. Arnulf's expedition into Moravia in 892 opened a period of troubles, which increased when Arnulf made an alliance with the Magyars of Hungary. Svatopluk's successor, Mojmír II, tried unsuccessfully to protect his patrimony; sometime in 905–908 Great Moravia ceased to exist as an independent country.

(E.Wn./O.O.)

Slovakia. The country was inhabited in the first centuries AD by Illyrian, Celtic, and then Germanic tribes. The Slovaks—Slavs closely akin to, but possibly distinct from, the Czechs—probably entered it from Silesia in the 6th or 7th century. For a time they were subject to the Avars, but in the 9th century the area between the Morava River and the central highlands formed part of Great Moravia, when the Slovak population accepted Christianity from Cyril and Methodius. In the 890s, however, the German king Arnulf called in the Magyars to help him against Moravia, and Slovakia lay in their path. The Moravian state was destroyed in the first decade of the 10th century, and after a period of disorder Slovakia became one of the lands of the Hungarian crown in the 11th century.

The main ethnic frontier between Magyars and Slovaks ran along the line where the foothills merge into the plain, though there were also Magyars settled in the larger valleys; later, the landlord class and much of the urban population in the whole area was Magyar. On the other hand, as the country suffered from chronic overpopulation, a constant stream of Slovak peasants moved down into the plains, where they usually were Magyarized in two or three generations.

(E.Wn.)

THE PŘEMYSLID RULERS OF BOHEMIA (895–1306)

The prince of Bohemia made an accord with Arnulf (895) and thereby warded off the danger of invasion. The domain over which the descendants of Přemysl ruled from the Prague castle was, in the early 10th century, the largest unit in Bohemia. The tribal chieftains who opposed centralistic tendencies exercised control over the eastern and northeastern districts, but the extent of their power is not known. The most powerful of them, the Slavníks residing at Libice, remained defiant until the end of the 10th century.

Bohemia maintained close relations with neighbouring Bavaria. Both countries were threatened for several decades by the Magyars, and other developments in their vicinity also affected political and social life. The most important of these was the rise in Germany of the Saxon dynasty, which began with Henry I the Fowler; the imperial coronation of Otto I in Rome (962) marked the restitution of the Holy Roman Empire, with which Bohemia was linked thereafter for many centuries. Bohemia's reorientation toward the Saxon dynasty began under the grandson of Bořivoj, Wenceslas I (Václav, ruled 921–929); it was symbolized by the dedication of a stone church at the Prague castle to a Saxon saint, Vitus. Both Slavic and Latin legends praise Wenceslas as a fervent Christian believer but tell little about his political activities. He was murdered by his younger brother Boleslav, and soon afterward he became regarded as the patron saint of Bohemia. The legends present the murder as an outburst against Wenceslas' devotion to the new faith, but the conspiracy probably also had a political motivation.

Restitution of the Holy Roman Empire

Boleslav I (ruled 929–967) reigned as a Christian prince; his daughter married Prince Mieszko I of Poland and helped spread Christianity in that country. Boleslav attempted, unsuccessfully, to loosen the ties with the Saxon dynasty. Boleslav II (ruled 967–999) used friendly relations with the pope and the emperor to enhance his prestige. He attached new territories east of Bohemia to his father's annexations. In 973 a bishopric was founded in Prague and subordinated to the archbishop of Mainz. The first bishop, Thietmar, was from the Saxon land but knew the Slavic language; he was succeeded in 982 by Adalbert (Vojtěch), a member of the Slavník family. Adalbert's promotion can be viewed as an attempt to harmonize relations between the Prague and Slavník princes, but that result did not materialize. Legends hint that Adalbert encountered considerable opposition when attempting to raise the standards of religious life in his diocese, and tension between the rival dynasties showed no signs of abating. In 995

Boleslav II moved against the Slavníks and broke their power. Adalbert enjoyed some initial success among the heathen Prussians on the shores of the Baltic Sea but then suffered a martyr's death in 997.

Struggles among the descendants of Boleslav II plagued the country for about 30 years and considerably reduced its power. Most of the territories attached to Bohemia in the 10th century were lost. Prince Břetislav I, a grandson of Boleslav II, led a successful expedition into Moravia; he conquered only a minor portion of the former Great Moravia, but it was large enough to constitute a province, and it was linked from then on with Bohemia. However, the ambitions of Břetislav, who was enthroned in 1034, ran higher. He invaded Poland in 1039 with only temporary success; he incurred the indignation of the German king Henry III and was forced to evacuate the conquered territory and to make an oath of fealty (1041). In the latter part of his reign, Břetislav cooperated with Henry III, thus protecting his domain against armed intervention.

The entire territory of Bohemia and Moravia was regarded as a patrimony of the house of Přemysl, and no emperor attempted to put a foreign prince of his own choice on the throne. But the ruling family grew large, and after Břetislav's death (1055) it became entangled in competition for primacy. For about 150 years the course of public life in Bohemia was largely determined by dissensions among the adult princes, some of whom ruled in portions of Moravia under Prague suzerainty. The emperors and the landowning magnates exploited the conflicts to promote their selfish interests. A key problem was the absence of any strict law of succession; the principle of seniority usually conflicted with the reigning prince's desire to secure the throne for his oldest son.

The territory's minor obligations toward the emperors were a handicap under weak princes or when the male members of the ruling family were at odds, but a strong prince could turn friendly relations with the empire to his advantage. Břetislav's second son, Vratislav II (ruled 1061–92), as a compensation for services rendered, obtained from Emperor Henry IV the title of king of Bohemia (1085). Another able ruler, Vladislav I, gained the dignity of a cupbearer to the emperor (1114), one of the highest court offices; as its holder, the prince of Bohemia became one of the electors who chose the Holy Roman emperor. Vladislav II (ruled 1140–73) participated in the campaigns of Frederick I Barbarossa in Italy. He was named king and crowned by the emperor at Milan in 1158.

Vratislav II

Active participation in imperial policies and military campaigns reduced markedly the Czechs' isolation, caused by Bohemia's geographic position. Other contacts were made with foreign merchants and with clerics who came from abroad or who were traveling from Bohemia to Rome and to famous shrines. By the early 11th century, the Latin rite prevailed. Cosmas of Prague, who recorded in his chronicle the history of Bohemia to 1125, was an ardent supporter of the Latin liturgy. Western orientation of the hierarchy and of the monastic orders was documented by the prevalence of Romanesque architecture, of which notable examples could be found in Prague and in the residences of lesser members of the ruling family. In social stratification and in economy, the country reached such a degree of consolidation that it withstood, without serious damage, the political struggles that ravaged it in the late 12th century.

Frederick I helped foment discord among Přemysl's descendants. In 1182 he reduced the dependence of Moravia on the Prague princes and subordinated that province to his imperial authority. In 1187 he exempted the Prague bishop, a member of the Přemysl family, from the jurisdiction of the ruling prince and made the bishopric an imperial fief. These decisions had no lasting significance, however, and the Přemysl patrimony survived. The period of trials closed with Frederick's death (1190). Frequent subsequent changes on the imperial throne lessened the danger of intervention. During the same period, the Přemysl family was reduced to one branch, so that the problem of succession lost its pressing importance. In 1198 the Přemysl duke Otakar I received the royal title for himself and his descendants from one of the competitors for the imperial crown. A solemn confirmation occurred in 1212, when Frederick II issued a charter known as the Golden Bull of Sicily, which regulated the relationship between Bohemia and the empire. The king's obligations were reduced to a minimum, but as elector he was able to exercise perceptible influence, ranking first among the temporal members of the college of electors.

The Golden Bull of Frederick II

Under Otakar I and his successors, Bohemia moved from depression to political prominence and economic prosperity. The original socioeconomic structure was giving way to a more developed stratification. The clergy gained independence from temporal lords in 1221. The landowning class, made up of wealthy lords and less-propertied squires, claimed freedom in administering their domains and a more active role in public affairs. In the early 13th century the population of Bohemia and Moravia increased noticeably through immigration from overpopulated areas in Germany. Many of the German-speaking newcomers were encouraged by the kings to found urban communities or to develop mining, especially of silver. The landowning magnates and the ecclesiastical institutions followed the royal example and settled the immigrants on their estates. There thus came into existence an urban middle class that enjoyed valuable privileges, especially the use of German law, and that became only slowly amalgamated with the native population. Apart from the townsfolk, German farmers moved into Bohemia and Moravia and transformed the less attractive border districts into prosperous areas. German immigration continued under Otakar I's successor, Wenceslas I (ruled 1230–53), and reached its peak under Otakar II (ruled 1253–78). Bishop Bruno of Olomouc, in cooperation with the king, promoted colonization of large tracts of land in northern Moravia.

Otakar II was a strong and capable ruler who obtained possession of Austrian lands through marriage, and in 1260 he was invited by the nobility of Styria to become their lord. Personal bravery and financial resources facil-

Přemyslid expansion under Otakar II and his successors (1253–1306).

itated his penetration into other Alpine provinces. Before his opponents could combine forces to check his advance, Otakar II had exercised influence in Carinthia as well as in some territories along the Adriatic coast. His expansion aroused the hostility of the kings of Hungary; but even more dangerous was Rudolf, count of Habsburg, who was elected king of the Romans in 1273 and, to secure a foothold in central Europe, claimed the Austrian lands as vacant fiefs of the empire. War followed and ended in Otakar's defeat in 1276. Otakar was unwilling to accept the loss of Austria as final, however, and began a new campaign. Not only Rudolf's army but also Hungarian troops moved against the Czech forces, and a group of noblemen, most of them from southern Bohemia, sided with the enemy. Otakar was too weak to resist the unexpected coalition against him, and, on Aug. 26, 1278, at Dürnkrut, Austria, he lost both the battle and his life.

Otakar's only son, Wenceslas II (ruled 1278–1305), was too young to take control immediately. During the period following Otakar's death (remembered as the evil years), Wenceslas was a mere puppet in the hands of ambitious lords, but in 1290 he emancipated himself from the tutelage and ruled with more success than had his father. The country was recovering quickly from both political and economic depression, and it again played an active role in international relations. Instead of resorting to wars, Wenceslas engaged in negotiations and soon achieved success in Upper Silesia. This was a prelude to his penetration into Poland, which culminated in 1300 with his coronation as its king. Diplomatic dexterity and enormous wealth quickly enhanced Wenceslas' prestige. In 1301 he was considered a candidate for the vacant throne of Hungary, but he recommended his son as a candidate instead. Meanwhile, the mines in various parts of the country, particularly at Kutná Hora, yielded so much silver that the king was able to reform the monetary system and issue coins (*grossus*), which soon circulated within and outside his kingdom. Wenceslas II's acquisitions, however, were lost soon after his death; his son Wenceslas III took over Bohemia but was assassinated on his way to Poland (1306). Thus ended the long rule of the Přemysl family.

The end of the Přemysl dynasty

THE LATE MIDDLE AGES (1310–1526)

The Luxembourg dynasty. After a four-year struggle for the throne, the Bohemian magnates decided for John of Luxembourg, son of Henry VII, the king of the Romans. John, only 14, married Elizabeth (Eliška), the second daughter of Wenceslas II. John confirmed the freedoms that the Bohemian and Moravian nobles had usurped during the interregnum and pledged not to appoint aliens to high offices. Nevertheless, a group of advisers, headed by Archbishop Petr of Aspelt, followed John to Prague and tried to uphold the royal authority. In the resulting conflict, a powerful aristocratic faction scored a decisive victory in 1318. Its leader, Jindřich of Lípa, virtually ruled over Bohemia until his death in 1329. John found satisfaction in tournaments and military expeditions, and he attached to Bohemia some adjacent territories; the extension of suzerainty over the Silesian principalities was his most significant achievement. He was assisted late in his reign by his oldest son, Wenceslas, who was brought up at the French royal court, where he changed his name to Charles. Charles endeavoured to raise the prestige of the monarchy but was hindered by John's jealousy and by lack of cooperation among the nobility. In 1346 both John, then blind, and Charles joined the French in an expedition against the English. John fell at Crécy, in France.

John and Charles benefited from friendly relations with the popes at Avignon. In 1344 Clement VI elevated the see of Prague and made Arnošt of Pardubice its first archbishop. Clement VI also promoted the election, in 1346, of Charles as the king of the Romans. In Bohemia, Charles ruled by hereditary right. To raise the prestige of the monarchy, he cooperated with the nobility and the hierarchy. He made Bohemia the cornerstone of his power and, by a series of charters (1348), settled relations between Bohemia, Moravia, and other portions of his patrimony. He acquired several territories in the vicinity at opportune times by purchase or other peaceful means. At the end of his reign, four incorporated provinces existed in union with Bohemia: Moravia, Silesia, Upper Lusatia, and Lower Lusatia. Charles also confirmed earlier documents defining the position of Bohemia in relation to the empire. In 1355 he was crowned emperor in Rome as Charles IV. After consultation with the electors, Charles issued the Golden Bull, which remedied some of the political problems of the empire, especially the election of the emperor.

Under Charles, Prague became headquarters of the imperial administration. By the foundation of a new district (*nové město*), Charles facilitated expansion of the city as well as a rapid increase in its population; about 30,000 people lived there by the latter part of his reign. In 1348 he founded in Prague a university with four traditional divisions (theology, law, medicine, and liberal arts); its members were grouped into four nations (Bohemian, Bavarian, Saxon, and Silesian-Polish). Prague attracted scholars, architects, sculptors, and painters from France, Italy, and German lands; the most distinguished among them was the architect Petr Parléř (d. 1399), a native of Swabia. The flourishing of the late Gothic architectural style left a deep mark on both the royal residence and the countryside. Under Charles, Bohemia was spared entanglements in war and reached a high level of prosperity, shared by the upper classes and the peasantry. Charles was eager to save the power and possessions accumulated since 1346. He succeeded in getting his son Wenceslas crowned king of the Romans in 1376. He also made provisions for dividing the Luxembourg patrimony, with the understanding that its male members would respect Wenceslas as their head. After Charles's death (1378) a smooth transition to Wenceslas' reign appeared to be assured. The country mourned Charles as "the father of the country."

Prague under Charles I

His heir began to rule, without opposition, as Wenceslas IV. Although not without talents, he lacked his father's tenacity and skill in arranging compromise, and in less than a decade the delicate balance between the throne, the nobility, and the church hierarchy was upset. In a conflict with the church, represented by Jan of Jenštein, archbishop of Prague, the king achieved temporary success; the archbishop resigned and died in Rome (1400). The nobility's dissatisfaction with Wenceslas' regime was serious, mainly over the selection of candidates for high offices, which wealthy families regarded as their domain and to which Wenceslas preferred to appoint gentry or even commoners. The struggle was complicated by the participation of other Luxembourg princes, especially Wenceslas' younger brother Sigismund. The nobles twice captured the king and released him after promises of concessions. But Wenceslas never took his pledges seriously, and the conflict continued. Simultaneously with the troubles in Bohemia, discontent with Wenceslas was growing in Germany. In 1400 the opposition closed ranks; the electors deposed Wenceslas and elected Rupert of the Palatinate as emperor.

The turn of the century was a watershed in reform endeavours in Bohemia. The movement arose about 1360 from various causes, one of which was the uneven distribution of the enormous wealth accumulated by the church in a comparatively short time. Moral corruption infected a large percentage of the clergy and spread also among the laity. Prague, with its large number of clerics, suffered more than the countryside. Both the king and the archbishop showed favours to zealous preachers like Conrad Waldhauser and Jan Milíč of Kroměříž, but exhortations from the pulpit failed to turn the tide. The Great Schism in Western Christendom after 1378 weakened the central authority. Disharmony between Wenceslas and Jan of Jenštein hindered the application of effective remedies. In the late 14th century the reform movement was centred at Bethlehem Chapel (Betlémská Kaple) in Prague; its benefactors stressed preaching in Czech as the main duty of its rector.

The second, more dramatic, period of the reform movement began with the appointment in 1402 of Jan Hus to the pulpit at Bethlehem Chapel. A scholar, he combined preaching with academic activities and thus was able to reach the Czech-speaking masses and to group around

Jan Hus

himself scholars and students dedicated to the idea of reform. The university was split, because foreign members followed the conservative line. Another cause of division was the popularity of John Wycliffe, an English ecclesiastical reformer, among the Czech masters and students. Hus did not follow Wycliffe slavishly but shared with him the conviction that the Western church had deviated from its original course and was in urgent need of reform. Hus enjoyed the goodwill of Zbyněk Zajíc, archbishop of Hazmburk. The atmosphere in Prague deteriorated rapidly, however; the German members of the university allied with Czech conservative prelates, led by Jan Železný ("the Iron"), bishop of Litomyšl. Because Wenceslas favoured the reform party, its opponents pinned hopes on Sigismund, king of Hungary; Wenceslas was childless, and Sigismund had a fair chance of inheriting Bohemia.

In the winter of 1408–09, a strong group of cardinals convened a general council at Pisa, which deposed the two rival popes and elected Alexander V to fill the vacancy. Wenceslas sympathized with the cardinals and invited the university to join him. When the Germans did not respond favourably, he issued, in January 1409 at Kutná Hora (Kuttenberg), a decree reversing the traditional distribution of votes. Thereafter, the three "foreign" nations had one vote and the Bohemian nation had three. The Germans rejected the decree and moved to Leipzig, where some of them unleashed a polemical campaign attributing to Hus more influence on the king than he actually had and depicting him as the chief champion of Wycliffe's ideas. Meanwhile, Alexander issued a bull virtually outlawing Hus's sermons in Bethlehem Chapel and authorizing rigid measures against discussion of Wycliffe's ideas. Hus and his collaborators continued their activities. Neither Wenceslas nor any of the Czech prelates was experienced enough to achieve reconciliation between the church authorities and the reform party, and Bohemia was drawn into a sharp conflict. In 1412 the antipope John (XXIII) became involved in a war with the king of Naples and offered indulgences for contributions to the papal treasury. When Hus and his friends attacked the questionable practices of papal collectors in Prague, John put Prague under interdict. Hus, hit by the sentence of excommunication, left Prague and moved to the countryside under the protection of benevolent lords.

In 1414 John, acting in harmony with Sigismund (who since 1411 had been the king of the Romans), called a general council to Constance (modern Konstanz, Ger.). Hus went there hoping to defend himself against accusations of heresy and disobedience. A safe conduct from Sigismund did not protect him in Constance. Late in November he was imprisoned and was kept there even after John, who had lost control of the council, had fled and been condemned by the cardinals. In the spring of 1415, Hus was called three times before the council to hear charges, supported by depositions of the witnesses and by excerpts from his own writing. The council paid no attention to Hus's protests that many of the charges were exaggerated or false. Hus refused to sign a formula of abjuration; he was then condemned and handed over to temporal authorities for execution. He was burned at the stake on July 6.

Execution of Hus

Some scholars reduced to a small number the points on which Hus had deviated from the official doctrine. But his followers, not interested in doctrinal subtleties, reacted emotionally against the council, Sigismund, and the conservative clergy. A wave of indignation swept over Bohemia and Moravia, and this movement, taking the name Hussite from the martyred leader, grew rapidly. A letter of protest, signed by 452 members of the nobility, was dispatched to Constance in September 1415. The condemnation and burning of Hus's friend Jerome of Prague (May 1416) increased the discontent.

Hus had not evolved a system of doctrine nor had he designated his successor. The most faithful of his disciples, Jakoubek of Stříbro, was not strong enough to keep the movement under his control. Ideological differentiation set in and resulted in divisions and polemics. The moderate Utraquists were entrenched in Prague; the radicals came mostly from smaller boroughs and the countryside. The Germans in Bohemia and in the incorporated provinces remained faithful to the church, and, thus, the deep-seated ethnic antagonism was accentuated.

After the death of Wenceslas IV (1419), political issues gained in importance. The Hussites were resolutely opposed to Sigismund, but the Czech Catholics and the Germans were willing to recognize him. Sigismund, determined to break the Hussite opposition, initiated a period of bitter struggles that lasted more than 10 years. Sigismund had the support of opponents of Hussitism within the kingdom, of many German princes, and of the papacy. Invasions of Bohemia assumed the character of crusades but were pushed back by the Hussites, who pulled together in times of danger.

The moderate Utraquists and the radicals reached agreement on the fundamental articles of their faith. The radicals built themselves a centre, given the biblical name Tábor. The accord, concluded in 1420 in the nation's capital, became known as the Four Articles of Prague; it stressed that (1) the word of God should be preached freely, (2) the communion should be administered in both kinds (*i.e.*, both bread and wine) to clerics and laypersons, (3) worldly possessions of the clergy should be abolished, and (4) public sins should be exposed and punished. A wide range of disagreements between Prague and Tábor was left open and often resulted in mutual accusations and embitterment. A third party arose in northeastern Bohemia, around a newly founded centre at Oreb, but it had a much smaller following than either Prague or Tábor.

Meetings were held at which attempts were made to give the country a national government; the most significant was an assembly at Čáslav (June 1421). A regency council was set up, but it lacked sufficient authority, and the virtual master of the country was the leader of the "warriors of God," Jan Žižka. He was originally attached to Tábor, but he became disgusted with the endless disputes of its theologians and left the radical stronghold to organize a military brotherhood in northeastern Bohemia (1422); its members became so devoted to Žižka that after his death (1424) they called themselves Orphans.

Žižka strove tenaciously for two goals—the protection of Bohemia from Sigismund and the suppression of the enemies of the law of God within Bohemia and Moravia. He scored brilliant victories in battles against Sigismund's forces but could not unite the country under his banner. A Roman Catholic minority, stronger in Moravia than in Bohemia, resisted the overtures of the Hussite theologians and Žižka's attacks. After Žižka's death, his heirs, headed by Prokop Holý the Shaven, lost interest in protracted warfare with Catholic lords and undertook instead foraging raids into the German territories bordering on Bohemia. Whenever a crusade menaced Bohemia, however, the radical military brotherhoods joined the conservative forces to push back the invader. The last encounter at Domažlice was bloodless; the crusaders fled in panic upon hearing of the Hussite strength.

Meanwhile, a general council of the church met at Basel, Switz., in 1431 and determined to find a peaceful settlement. At a conference at Cheb (1432), the delegates from Basel and the Hussite spokesmen resolved that in controversial matters "the law of God, the practice of Christ, of the apostles and of the primitive church" would be used to determine which party holds the truth. The Hussite envoys reached Basel and opened debate on the cardinal points of their doctrine. It soon became clear, however, that the council was unwilling to abide by the Cheb agreement and that theologians representing the Tábor and Orphan brotherhoods would not acquiesce to a lean compromise.

A drastic change occurred in Bohemia in 1434. In a fratricidal battle at Lipany in May, combined Catholic and Utraquist forces defeated the radicals and took control of the country. Under the leadership of Jan Rokycana, dealings with the Council of Basel advanced markedly. The final agreement came to be known as the Compacts (Compactata); it followed the Four Articles of Prague but weakened them with subtle clauses (*e.g.*, the council granted the Czechs the communion in both kinds but under vaguely defined conditions). After the promulgation of the Compacts (July 1436), an agreement followed with

The Compacts

Sigismund. But he died in 1437, and Bohemia was neither united in religion nor consolidated politically.

Various forces hindered religious pacification. The Catholic clergy refused to respect the Compacts, because they were not sanctioned by the pope and would not accept Rokycana as archbishop. The radical parties, although gravely weakened at Lipany, existed as an uncompromising opposition to Rokycana. His bid for recognition was also defied by the right Utraquist wing, which had seized the key positions during Sigismund's brief reign.

The Hussite preponderance. Sigismund had no son, and the problem of succession caused a split among the nobility, which had been enriched during the revolutionary era by the secularization of church properties and had grown accustomed to the absence of monarchy. The conservatives accepted Sigismund's son-in-law Albert II of Austria, but the more resolute Hussites favoured a Polish candidate. Albert's death in 1439 ushered in another interregnum. In January 1440 an assembly was held to set up provincial administration for Bohemia; its composition demonstrated clearly the steady rise in the importance of the wealthy lords, functioning as the first estate. The lesser nobility, recognized as the second estate, was large in number; although the percentage of Catholics among the lords was rather high, the second estate was predominantly Hussite and conscious of its contributions to the Hussite defense. The upper classes recognized the royal boroughs as the third estate but were increasingly more reluctant to share power with them. In the January assembly the political alignments were not identical with religious divisions. Some moderate Catholics cooperated with the Utraquist majority, headed by Hynek Ptáček of Pirkštejn; a group of conservative Utraquists joined the Catholic lords, among whom Oldřich of Rožmberk held the primacy. The actual leader of the conservative bloc was Menhart of Hradec, nominally a Utraquist. No one was elected governor of Bohemia. Instead, in the counties into which Bohemia was subdivided, leagues were organized to promote cooperation of local lords, knights, and royal boroughs, irrespective of religious orientation.

The problem of succession became urgent when Albert's widow, Elizabeth, gave birth to a boy, baptized Ladislas and called Ladislas Posthumus. Several foreign princes showed an interest in the throne, but in 1443 the estates recognized Ladislas' claims. As he resided at the court of his guardian, the German king Frederick III, the interregnum was extended. Ptáček, who headed the majority, died in 1444, and the party acclaimed George of Poděbrady as its leader. For several years the destiny of Bohemia was determined by the efforts of Oldřich of Rožmberk and his allies to obstruct George's endeavours. Apart from political and economic stabilization, George strove for a papal sanction of the Compacts and for the confirmation of Rokycana as archbishop. George realized that Menhart's domination of Prague was a more serious obstacle than Rožmberk's intrigues; in 1448 George attacked and took Prague without bloodshed. Rokycana also entered the city and took over from the archconservatives the Utraquist (or Lower) consistory. Although Frederick III was of the same religion as Rožmberk, he realized that an alliance with George would improve Ladislas' chances; in 1451 Frederick designated George governor of Bohemia. From that position of strength, George moved energetically against both the Rožmberk coterie and the remnants of the radicals, entrenched at Tábor.

In October 1453 Ladislas was crowned king in St. Vitus' Cathedral, and George served as his chief adviser. Ladislas had been brought up as a Roman Catholic, and German was his mother tongue. George hoped the king could reestablish Bohemia's connection with the incorporated provinces, especially the populous and rich Silesia. Ladislas died suddenly in November 1457. Several foreign princes competed for the throne, but the estates of Bohemia reaffirmed the elective principle and decided unanimously for George (March 1458).

Election of George of Poděbrady

Although attached to the Utraquist party, George endeavoured to rule as a king of "two peoples": the Utraquists and the Catholics; the Czechs and the Germans. He was eager to be crowned according to the rites prescribed by Charles IV. George's son-in-law, King Matthias of Hungary, sent two bishops to Prague; George took a secret oath in their presence, by which he obliged himself to defend the true faith and to lead his people from errors, sects, and heresies. Because the Compacts were not mentioned, George did not hesitate to make his pledge; since the agreement with the Council of Basel, the Utraquists considered the communion in both kinds as a lawful concession and not a heresy. Because both the election and coronation took place in Prague, George's principal concern was to have his title recognized by the estates of the incorporated provinces. He was mostly successful, but he had to accept the friendly help of papal envoys to get at least a provisional recognition by the Catholic and predominantly German city of Breslau (modern Wrocław, Pol.) in Silesia (1459). During the next three years George enhanced his prestige both at home and abroad. Feeling that no lasting peace could be achieved without the speedy settlement of religious issues, George attempted in 1462 to have the Compacts sanctioned by Pope Pius II. Instead of approving the Compacts, the pope declared them null and void. When informed of the pope's action, George held a solemn assembly in Prague in August and affirmed his devotion to the communion in both kinds. Although neither the pope nor the king showed any intention of retreating from his position, armed conflict was not inevitable, and several princes, including Frederick III, were willing to use their influence to arrange a compromise. But a new pope, Paul II, was elected in 1464 and soon adopted an aggressive policy that encouraged George's foes, especially the city of Breslau. A group of Catholic noblemen from Bohemia, headed by Zdeněk of Šternberk, formed a hostile league at Zelená Hora (1465) and entered into negotiations with Breslau and other Catholic centres. Shortly before Christmas 1466 the pope excommunicated George and released his Catholic subjects from their oath of allegiance. In spring 1467 George's troops attacked the rebel forces. George was, on the whole, successful in desultory campaigns against the castles of the insurgents, but his position became more awkward in the spring of 1468 when Matthias of Hungary brought support to the Czech rebels. The Hungarians invaded Moravia and, by tying down a considerable portion of the royal army, they facilitated rebel successes in other parts of the kingdom. In May 1469 the opposition proclaimed Matthias king of Bohemia. In 1470 George achieved some successes over his rivals, but he was unable to consolidate them because of deteriorating health. He died in March 1471, mourned by both the Utraquists and loyal Catholics.

The Jagiellonian kings. The Holy Roman emperor Frederick III had observed benevolent neutrality. George also had derived comfort from the friendly disposition of Casimir IV, the Jagiellonian king of Poland. Contacts with the Polish court continued after George's death and resulted, in May 1471, in the election of Casimir's son, known in Bohemia as Vladislas II, as king of Bohemia. Vladislas was supported by George's partisans irrespective of religious affiliation. George's foes adhered to Matthias, who possessed Moravia, Silesia, and the Lusatias. Vladislas' forces were not strong enough to defeat the rival, and an agreement concluded in 1478 enabled Vladislas to consolidate his position in Bohemia but left Matthias in temporary possession of the incorporated provinces. After Matthias' death (1490) Vladislas was elected king of Hungary (as Ulászló II); thus, he was able to reunite the incorporated provinces with Bohemia. Vladislas' successor was his only son, Louis, a sickly boy nine years old at his father's death.

Decline of royal authority

The reign of the two Jagiellonians was marked by a decline of royal authority. Vladislas II had been brought up as a Catholic and made no secret of his dislike of the Utraquist rites. By his coronation oath, however, he obligated himself to respect the Compacts. As long as Matthias was alive, Vladislas was supported chiefly by the Utraquists. After 1490 he spent more time in Hungary than in Bohemia, as did Louis. In this latter period the Catholic lords attached themselves to the royal court and exercised strong influence on the public affairs of Bohemia.

The Jagiellonian era at first appears to have been an

unbroken chain of aristocratic feuds and rivalries in which personal ambitions triumphed over patriotic sentiments, but a closer examination reveals brighter spots and concrete examples of constructive cooperation. The king stood aloof, and the Catholic and Utraquist factions of the estates concluded an agreement at Kutná Hora (March 1485) that reaffirmed the Compacts, recognized the existing divisions in Bohemia, and forbade attempts by either party to extend its sphere of influence at the expense of the other. The accord lasted until 1516 but was renewed in 1512 as "of perpetual duration." The Unity of the Czech Brethren, which had come into existence in 1457–58 as a new expression of Hussite rigorism, was not granted legal protection. In 1508 Vladislas II issued a stern decree, ordering persecution of the Unity, but it was not applied too rigidly.

The provincial diet rather than the royal court held primacy under the Jagiellonians, especially when the kings resided at Buda (modern Budapest). The lords dominated the diet and were supported by the lesser nobility when attempting to limit royal power or when introducing restrictive measures against the lower classes. Both the mighty lords and the less propertied knights viewed with displeasure the political aspirations of the royal boroughs, their competitors in commerce and production. The diets passed several resolutions to remove the third estate from the positions acquired during the Hussite revolution. Because the boroughs obtained little help from the sovereign and his officers, the nobility encountered little resistance. A land ordinance adopted by the diet in 1500 limited considerably participation of the boroughs in the diet. The boroughs also were hit by several decrees, approved by the diet (especially those of 1487 and 1497), by which the landowners attached the peasantry to their estates. They thus reduced the possibility of migration into the towns and deprived the towns of cheap labour.

The boroughs, prosperous and self-confident, resisted the limitations and sought allies wherever they could be found. They obtained some concessions under Vladislas II, but a general compromise was made by the diet held in 1517 by which the boroughs joined concessions in political and administrative matters and surrendered some of the earlier privileges on which their economic prosperity was based. The higher estates tacitly recognized the right of the royal boroughs to participate in the diet as the third estate but reserved for themselves the positions on the board of provincial officers, including that of the vice chamberlain, who, in the king's name, supervised municipal administration. Although the boroughs gained some reasonable satisfaction, the landowning nobility was permitted to engage in production of articles that were previously the monopoly of the royal boroughs.

Compromise between the nobles and the boroughs

The agreement of 1517 did not end feuds and conflicts among the aristocratic factions and their partisans in the lower classes. In 1522 the Hungarian king Louis II left for Prague, intending to heighten the royal authority. With the help of loyal lords, he relieved Zdeněk Lev of Rožmitál of the office of supreme burgrave in February 1523 and appointed Karel of Minstrberk, a grandson of George of Poděbrady, to that key position in provincial administration. Soon after the king's departure, however, Rožmitál resumed political activity and searched for allies. Religious controversies that flared up soon after Martin Luther's attack on indulgences (October 1517) increased tensions in Bohemia. Rožmitál, posing as a staunch supporter of the old faith, ingratiated himself with the king and regained his office. Louis, fully occupied with Hungarian affairs, was preparing for a campaign against the Turks. Meeting the Turkish army with inadequate forces, Louis was defeated; he drowned in the marshes near Mohács, Hung., while retreating from the battlefield (August 1526).

HABSBURG RULE (1526–1914)

The Habsburgs to 1848. Ferdinand I of Habsburg, the husband of Louis's sister Anne, presented his claims to the vacant throne. He made substantial concessions to the Bohemian magnates and was elected king in October 1526; the coronation took place in February 1527. Ferdinand also ruled in other countries and, beginning in 1531, he assisted his brother, the emperor Charles V, in imperial affairs. After Charles's resignation (1558) Ferdinand was elected emperor. He considered Bohemia his most precious possession.

Early in his reign, Ferdinand was frequently absent, but when he was in Bohemia, he endeavoured to dilute his precoronation pledges and curtail the privileges of the estates. He was obliged by the coronation oath to observe the Compacts and to treat the Utraquists as equal to the Catholics. But since 1517 Bohemia had been open to ideas emanating from Wittenberg and other Reformation centres. Lutheranism had adherents among the Utraquists and among the German-speaking inhabitants of Bohemia and Moravia. The Unity of the Czech Brethren resisted successfully repeated attempts at its extermination; although not protected by the Compacts, the Unity increased in numbers and was shielded by sympathetic landowners, some of whom became members. The teachings of radical reformers also had echoes in Ferdinand's domains.

An opportunity to settle controversial problems arose in 1547. During the Schmalkaldic War (1546–47), between the Habsburgs and the Protestant Schmalkaldic League, the estates of Bohemia pursued an inconsistent policy, and, after the Habsburg victory at Mühlberg (April 1547), Ferdinand moved quickly against them. The high nobility and the knights suffered comparatively mild losses, but the royal boroughs virtually lost their political power and were subordinated more rigidly to the royal chamber. Another target of the king's wrath was the Unity; significantly, Ferdinand's vindictive policy did not apply to Moravia, the estates of which were more cooperative during the Schmalkaldic War than were those of Bohemia. After 1547 the Unity flourished in Moravia, and its members, driven from Bohemia, moved to Moravia or emigrated to Poland.

Ferdinand's moves against the Bohemian estates

The Diet of 1549 approved Ferdinand's request that his firstborn son, Maximilian, be accepted as the future king. Ferdinand also resumed his scheme of religious reunion on the basis of the Compacts, but he soon realized that few Utraquists adhered to that outdated document. The majority, called Neo-Utraquists by modern historians, professed Lutheran tenets as formulated by Martin Luther's associate Philipp Melanchthon. Disheartened by the meagre results of his policy, Ferdinand turned toward the Catholic party to consolidate its organization. He introduced the newly founded and militant Society of Jesus (Jesuits) into Bohemia (1556) and obtained from Rome consecration of Antonín Brus of Mohelnice as archbishop (1561). Shortly before his death, Ferdinand succeeded in getting from Pius IV a sanction of the communion in both kinds, but the pope insisted on so many restrictions that his bull satisfied only the Utraquist extreme right.

Maximilian II (ruled 1564–76) was reluctant to grant free exercise of the Lutheran faith, which the majority of the estates requested in 1571. After several years of futile efforts, the estates adopted a more flexible policy. Both the Czech Neo-Utraquists and the German-speaking Lutherans came together and prepared a summary of their faith, known as the Bohemian Confession, which agreed in the main points with the Augsburg Confession. The Brethren cooperated with the adherents of the Bohemian Confession but preserved both their doctrine and their organization. In 1575 Maximilian II approved the Bohemian Confession, but only orally; it was commonly assumed that his oldest son, Rudolf, who was present at the session, would respect his father's pledge.

The Counter-Reformation in Bohemia. The early stage of Rudolf II's long reign (1576–1612) was simply an extension of Maximilian's regime. But in 1583 Rudolf transferred his court from Vienna to Prague, bringing with him the high offices and foreign envoys. The Bohemian capital became once more an imperial residence and a lively political and cultural centre. Rudolf, brought up in Spain, had sympathy only for the Roman Catholic faith. Because the crown possessions were too small to yield adequate income, he depended mostly on the estates, whose majority was Protestant; only the provincial diets had the power to approve increased taxation and to grant subsidies for interminable wars against the Turks. The Catholic party, stronger among the lords than among the lesser no-

bility and burghers, came under the influence of militant elements, trained in Jesuit schools, and listened attentively to the papal nuncios and Spanish ambassadors. Because of its long antipapal tradition and its political prominence, Bohemia had an important place in the strategy of the Counter-Reformation. The Catholics singled out the Unity as their first target. Although numerically weak, the Brethren exercised a strong influence on Czech religious life and developed lively literary activities (in Rudolf's reign they produced a translation of the Bible from the original languages, which was printed in a hamlet of Kralice on the domains of the lords of Žerotín and which came to be known as the Kralice Bible). The Catholics sought to create a breach between the majority party of the Bohemian Confession and the Unity.

By a succession of new appointments, Catholic radicals about 1600 occupied the key positions in the provincial administration of Bohemia; their head, Zdeněk Vojtěch of Lobkovice, served as the supreme chancellor and enjoyed Rudolf's confidence. In 1602 Rudolf issued a rigid decree against the Unity, which was enforced not only in the royal boroughs but also on the domains of fervent Catholic lords. The Brethren and also the more resolute adherents of the Bohemian Confession realized that the days of peaceful coexistence were gone. They closed ranks under the leadership of Václav Budovec of Budov, a prominent member of the Unity. Dissatisfaction with Rudolf's regime was growing rapidly in other Habsburg domains. His younger brother, Matthias, made contacts with the Austrian and Hungarian opposition; the Moravian estates, headed by Karel the Elder of Žerotín, joined Matthias. In 1608 rebel forces advanced to Bohemia; Rudolf was unable to resist them, and he made peace and transferred to Matthias the dissatisfied provinces. The Protestant estates of Bohemia used Rudolf's weakness for their own purposes. In July 1609, Rudolf reluctantly issued a charter, known as the *Majestát* (Letter of Majesty), that granted freedom of worship to the Catholics and to the party of the Bohemian Confession, with which the Brethren closely cooperated. Some passages of the charter were vague, and so the Protestant and Catholic estates concluded an agreement stipulating that future conflicts should be settled by negotiation. The Catholic radicals, too weak to upset the agreement, were unwilling to accept the *Majestát* as the final word in religious controversies.

In 1611 Rudolf was deposed, and Matthias was crowned king of Bohemia. Because he was childless, the question of succession was debated both in the court circles and among the estates. In 1617 Matthias presented his nephew Ferdinand of Styria to the Diet of Bohemia as his successor. The resolute faction among the Protestant nobility was caught unprepared and acquiesced in Ferdinand's candidacy, and he was accepted and crowned in St. Vitus' Cathedral. Opposition grew quickly to Ferdinand, who was suspected of cooperation with the irreconcilable opponents of the *Majestát*. In the spring of 1618 the Protestant estates decided on an action. Two governors of Bohemia, William Slavata and Jaroslav Martinic, were accused of violation of the *Majestát;* after an improvised trial they, together with the secretary of the royal council, were thrown from the windows of the Royal Chancellery in Hradčany Castle (May 23, 1618) but escaped with only minor injuries. This act of violence, usually referred to as the Defenestration of Prague, sparked a rebellion in Bohemia. The estates replaced the board, or royal governors, with 30 directors, who assembled troops for defensive purposes and gained allies in the predominantly Lutheran Silesia and in the Lusatias; the estates of Moravia were reluctant to join.

The Defenestration of Prague

The death of Matthias (March 1619) changed the situation profoundly. The directors refused to admit Ferdinand II into Bohemia. In Moravia the militant Protestant party overthrew the provincial government, elected 30 directors, and made an accord with Bohemia. At a general assembly of representatives of all five provinces, a decision was made to form a federal system. Ferdinand II was deposed, and Frederick V, elector of the Rhine Palatinate and a son-in-law of James I, king of England and Scotland, was offered the crown. He accepted and early in November 1619 was crowned king according to an improvised Protestant rite. Frederick's chances for success were slight; the population of Bohemia, especially the peasantry, was unenthusiastic in its support of the rebellion. Frederick received some financial help from the Netherlands, but German Protestant princes hesitated to become involved in a conflict with the Habsburgs, among whose allies were not only Catholic Bavaria but also Lutheran Saxony. In late summer 1620 Maximilian I of Bavaria coordinated the Catholic forces; the short battle on the White Mountain, at the gates of Prague (Nov. 8, 1620), had a decisive effect and delivered Bohemia to Ferdinand II. Frederick and his chief advisers fled from Bohemia. Fighting continued in 1621 at some isolated places and in Moravia, but no one succeeded in pushing back Ferdinand's troops.

In imposing penalties, the victorious Ferdinand treated Bohemia more harshly than he did the incorporated provinces. In June 1621, 27 leaders (3 lords, 7 knights, and 17 burghers) were executed. Landowners who had participated in any manner in the rebellion had much of their property confiscated. The upper estates and the royal boroughs were ruined; they ceased to function as centres of economic and cultural activities. Ferdinand rescinded the *Majestát* and declared his intention to promote the program of re-Catholicization of Bohemia and Moravia. The Jesuits, banned in 1618 by the directors, returned triumphantly and acted as the vanguard in the systematic drive against the non-Catholics, including the moderate Utraquists.

Absolutist rule. In 1627 Ferdinand II promulgated the Renewed Land Ordinance, a collection of basic laws for Bohemia that remained valid, with some modifications, until 1848; he issued a similar document for Moravia in 1628. Ferdinand settled, in favour of his dynasty, issues that had disturbed Bohemian public life since 1526: the kingdom was declared hereditary in both the male and female branches; the king had the right to appoint supreme officers; in the provincial diet the higher clergy was constituted as the first estate, and all the royal boroughs were represented by one delegate only; the diet lost legislative initiative and could meet only upon the king's authorization to approve his requests for taxes and other financial subsidies; the king could admit foreigners to permanent residence; and the use of German besides the traditional Czech was authorized. No faith other than Roman Catholicism was permitted.

Royal decrees pertaining to religion granted the upper classes the right to choose either conversion or emigration. A fairly high percentage decided for the latter and settled abroad, mostly in Saxony. Many peasants left the country illegally, especially during the Protestant invasions of Bohemia. The Czechs' most significant representative abroad was a scholar, John Amos Comenius (Jan Ámos Komenský). The majority of the population remained in the homeland and gradually converted to Roman Catholicism. The Jesuits became the most important force in Czech spiritual life. In 1654 their leading school, the Clementinum, was united with the remnants of Charles University. The Jesuits controlled not only higher education but also literary production. With an increasing number of Czech novices, the Jesuits could reach the common people, the majority of whom spoke only the Czech language.

Conversion of the Czechs to Roman Catholicism

The vacated places among the upper social classes were gradually filled by newcomers, most of whom obtained land as a compensation for services rendered to Ferdinand II and his successor, Ferdinand III (ruled 1637–57); some enterprising individuals purchased land in Bohemia either during or after the Thirty Years' War (1618–48). The old families and the newcomers had in common their attachment to the Roman Catholic church and to the dynasty; they intermarried and became amalgamated over the next several decades. German became the language in which public affairs were transacted. Language was not the only barrier separating the peasantry and lower middle class from the propertied noblemen and burghers, however. Both the victorious church and the wealthy laymen regarded the Baroque style as the most faithful expression of their religious convictions and their worldly ambitions.

For about 100 years, the Baroque dominated in architecture, sculpture, and painting and influenced literature, drama, and music. The external appearance of Prague and the smaller boroughs and towns changed markedly. In the countryside, sumptuous aristocratic residences contrasted sharply with the modest dwellings of the peasantry.

Leopold I (ruled 1657–1705) soon became involved in long and costly wars against the Turks and the French. Although Bohemia was not threatened by either of these enemies, its population had to share the financial burdens. The landed nobility was reluctant to accept financial obligation, so the major part of the contributions was expected to come from the burghers and the peasants. The urban communities, which had been impoverished during the Thirty Years' War, made no progress toward social and economic recovery. The lot of the peasantry was so heavy that uprisings occasionally took place, though with no chance of success. For the common people, the short reign of Joseph I (ruled 1705–11) brought some relief, but under his brother and successor, Charles VI (ruled 1711–40), their plight reached appalling dimensions. The court and the residences of the ranking aristocrats consumed vast sums of money, which had to be squeezed from the depopulated towns and poorly managed domains. At this time, the alienation of the masses of people reached its apex.

Retention of autonomy under the Habsburgs

The Habsburgs, ruling over Bohemia from 1620 to 1740, did not insist on its close union with their other domains. The kingdom of Bohemia, though under an absolutist regime, retained its autonomy. The two Lusatias were ceded in 1635 to Saxony; Bohemia, Moravia, and Silesia retained their provincial administration. Members of the local nobility were appointed to high offices. The supreme chancellor of Bohemia served as a link between the kingdom and the sovereign and resided in Vienna to facilitate communication with the court and various central agencies attached to it.

Although motivated primarily by dynastic interests, most of the reforms of Charles's daughter Maria Theresa (ruled 1740–80) improved the living conditions of the population. Soon after her accession, Bavaria and Prussia invaded the Habsburg territories. Charles Albert, elector of Bavaria, occupied a major part of Bohemia and was acclaimed king by a fairly strong party among the estates; but he could not establish himself permanently, and in 1742 he pulled his forces back. Three wars fought against Frederick II the Great of Prussia in 1741–63, mostly in Bohemia and Moravia, were more serious and costly. Finally, Maria Theresa acquiesced in the loss of the major part of Silesia. Small duchies that she was able to retain were constituted as a crown land of Silesia and remained closely connected with Moravia and Bohemia.

Realizing that the system inherited from Charles VI was the main source of weakness, Maria Theresa launched a program of administrative reforms (1749); its principal point was a closer union of the Bohemian crown land with the Alpine provinces. The queen's staunchest opponents were members of the landowning nobility who, up to that time, had controlled the provincial administration. In 1763 Maria Theresa made some concessions but would not abandon her centralist policy. The opposition did not remain united. The conservative faction remained unreconciled to the new course, but more flexible individuals accepted high positions in Vienna or in the provincial capitals and helped to build up the system, which Joseph II (ruled 1780–90) inherited from his mother and subordinated more rigidly to the sovereign's will and discretion.

Maria Theresa, partly under the influence of her husband, Francis Stephen of Lorraine, had adopted the idea of curtailing the privileges of the upper social classes so as not to conflict with the interest of the state, of which the ruler was the supreme representative. Joseph II had grown up in this enlightened atmosphere, and, when confronted with conservative opposition as king, he went far beyond his mother's limits. Apart from the administrative reforms, the judicial and fiscal systems were revamped to serve the enlightened monarch more adequately. The state extended its influence in such other fields as education, religion, landowner-tenant relationships, the economic recovery of the royal boroughs, and a more adequate distribution of the burden of taxes. The reforms did not aim at total abolition of social and economic distinctions, but they generally improved the lot of the lower middle class and of the peasant. Two decrees of 1781 made Joseph popular among the masses: he abolished restrictions on the personal freedom of the peasants, and he granted religious toleration. After the long period of oppression, these were hailed as beacons of light, although they did not go as far as enlightened minds expected. The edict of toleration in Bohemia and Moravia was not followed by a mass defection from the Roman Catholic church, partly because it did not refer to either the Utraquism or the Unity but rather authorized worship according to either the Augsburg or Reformed Confession.

Joseph's conservative successors, Leopold II (ruled 1790–92), Francis II (ruled 1792–1835), and Ferdinand V (Ferdinand I of Austria; ruled 1835–48), left intact the centralistic system inherited from Maria Theresa and Joseph II, but they did engineer a gradual transition from the manorial system to the full ownership of land by the peasants. They made peace with the landowning nobility, seeing in it their most faithful ally, but the provincial diets of Bohemia and Moravia still had no more than a decorative function. A fairly large number of persons of rank distinguished themselves as patrons of learning, lovers of theatre and music, promoters of new and more profitable methods of agriculture, and, in the early 19th century, pioneers of industry. In these activities they made contacts with gifted men of middle-class or peasant origin, gave them financial support, and shielded them from the ubiquitous police and rigid censorship. Provincial loyalties were stronger than ethnic differentiation, which emerged as a new factor in Bohemia about 1800 partly out of opposition to the centralistic tendencies of the Vienna court and partly under the impact of the French Revolution. Institutions destined to play an important role in the Czech national renascence, such as the Royal Bohemia Society of Sciences or the National Museum (1818), were bilingual and drew support both from the propertied German population and from a small fraction of the Czechs who became conscious of their origin, of the brighter periods, and of their kinship with other Slavic peoples.

Czech national renascence

From absolutism to constitutionalism. In 1848 the German-speaking population of Bohemia and Moravia had a distinct advantage over the Czechs. The upper classes of these two provinces were almost entirely German and the rural areas in which, after 1620, the Germans gained predominance extended from the mountain ranges deep into the lowlands, once purely Czech. There were, however, limited opportunities for Czechs of middle-class or peasant origin, who prepared for more lucrative occupations through higher studies or who acquired special skills. Some improvement could be observed in the last stage of Habsburg absolutism, from about 1830 on. The efforts of scholars, writers, clergymen, and schoolmasters, aware of their Czech origin, stirred a national consciousness among the common people. Not only the countryside but also the urban communities witnessed an awakening. The Habsburgs, symbolized by Prince von Metternich, tolerated no political activities but did not hinder cultural activities, the printing and distribution of nonpolitical books in Czech, theatrical performances, and gatherings for other than political purposes. The Czechs had their social and intellectual elite, small in number but devoted to the national cause, and they were shielded by a group of sympathetic aristocrats.

Similar conditions existed in the Hungarian counties inhabited by the Slovaks. Contacts between these two ethnic groups were hindered by the existence of provincial boundaries, but the groups were close enough to permit cultural exchanges. Up to 1840 the Czech language, regenerated by such eminent linguists as Josef Dobrovský and Josef Jungmann, was used by both Czech and Slovak authors. But the growing national awareness gave rise to endeavours to develop a literary language for the Slovaks in order to reach people with no more than elementary training. The Slovak literary language gradually replaced Czech among Slovak authors. Thus, the mounting wave

of nationalism created conditions for differentiation and for the establishment of two closely related but distinct ethnic units.

Revolution of 1848

In opposing Metternich's oppressive regime, the Czech intellectuals were allied with the progressive forces among the Germans. When the revolutionary wave reached Bohemia in March 1848, leaders of the two nationalities worked together in an attempt to shift from absolutism to constitutionalism. Both parties had a vague notion that Bohemia should return to its autonomous status and become a constituent part of the regenerated monarchy, but they could not resolve specific problems. The Germans saw advantages in cooperating with their kinsmen in other Habsburg lands; moreover, they were keenly interested in the idea of German unification, debated in the German constituent assembly at Frankfurt. The Czech voters looked to František Palacký as their leader; he had written several volumes of *A History of the Czech People* and was a respected political thinker. Palacký was assisted by Karel Havlíček Borovský, a journalist, and by František Rieger, a student of political science and economics. The Czech leaders sensed danger in the schemes laid before the Frankfurt assembly and in plans for a modernized but highly centralized Austria. Their primary concern was the Diet of Bohemia, and at times they included among their desiderata a general assembly of deputies from Bohemia, Moravia, and Silesia to stress a continuity of modern political efforts with the ancient kingdom. Despite some support from the aristocratic circles, however, the Czechs were unable to change the movement toward centralization.

A good deal of vacillation in and after 1848 was caused by the inability of Palacký and others to harmonize the emphasis of historical rights with genuine devotion to the principle of nationality. In late spring 1848 the idea of an elected diet for Bohemia was obscured by a loftier project, an assembly of spokesmen of the Slavic peoples from all parts of the Habsburg empire. No matter how sincerely Palacký and other prominent figures professed their loyalty to the ruling house, the Slavic congress was viewed with displeasure by the Germans and the Magyars and was finally dispersed by the archconservative Alfred, Prince zu Windischgrätz, who ordered that no election for the provincial diet could be held. The Czech leaders recognized that the constituent assembly meeting in July 1848 in Vienna was the only representative body before which they could express their aspirations. They participated in the late summer and early autumn sessions and worked with even more vigour when the assembly reconvened at Kroměříž (Kremsier). They made themselves allies of all factions that attempted to prepare the ground for a constitutional and federal system. Rieger, in particular, rose to the occasion when defending the principle that all power comes from the people. But the draft of a constitution for the Habsburg monarchy ran counter to ideas prevailing among the advisers of the new king Francis Joseph I (ruled 1848–1916). Early in March 1849 the Kroměříž assembly was dispersed. The Habsburg government, headed by Felix, Prince zu Schwarzenberg, ruled for some time in accordance with a constitution drafted by the crown advisers; but, on Dec. 31, 1851, Francis Joseph abolished the last vestiges of constitutionalism and began to rule as absolute master.

Movement toward centralization

The regime, allied with the church and supported by the army, police, and bureaucracy, was rigid and effective but tolerated no opposition. Its weakness was revealed, however, by the poor showing of its armies in a war with Sardinia in 1859. In October 1860 Francis Joseph issued a diploma burying the absolutist rule and inaugurating a constitutional era. It soon became clear, however, that no scheme forwarded by the crown advisers could reconcile the federalist tendencies with the monarch's desire to concentrate as much power as possible in Vienna.

After a war with Prussia and Italy in 1866, Francis Joseph sought a solution that would promise speedy recovery and the stabilization of internal affairs. In 1867 the monarchy was transformed into a dual system. The Magyars obtained the dominant position in Hungary, where Slovak ethnic identity was suppressed; in the conglomeration of other provinces, which was briefly called Austria, the Germans were the strongest single group, followed by Czechs, Poles, and other nationalities. The dual system passed through successive crises but remained in existence until 1918.

Like other nationalities, the Czechs resumed political activities after the promulgation of the October Diploma. Palacký was recognized as a dominant figure, but the actual leadership passed into Rieger's hands. Two courses were open to the Czechs: to apply the principle of nationality or to emphasize historical continuity. Palacký and Rieger decided for the latter and were supported by their conservative collaborators. Clearly, they had no chance for success without a close alliance with the conservative landed aristocracy, to which the electoral system granted a strong position in the provincial diets and in the parliament. But this alliance was exploited by Rieger's progressive opponents. Differentiation within the National Party began in 1863 and continued more rapidly after 1867. The Czechs, irrespective of ideological orientation, opposed the dual system and boycotted institutions that Austria received after the promulgation of a new constitution in December 1867. After two stormy years, an attempt was made to devise a solution that would give Bohemia autonomy within the Austrian half of the monarchy. In agreement with the historically minded nobility, Rieger negotiated in 1870 and 1871 with the Vienna cabinet and consented to a compromise. In October 1871 Francis Joseph, although originally sympathetic, yielded to heavy pressure from many sides and refused to sanction the compromise. No attempt was made to revive the project.

Despite this setback, Rieger was able to retain leadership for some 20 more years. Most official statements either in the Vienna Chamber of Deputies or in the provincial diets of Bohemia and Moravia contained a formal declaration in favour of the state right. The idea of restitution of the kingdom of Bohemia to its former rank, similar to that of Hungary, was never given up; but its chances of realization declined with the consolidation of the dual system, and Francis Joseph showed no intention of going to Prague to be crowned with the ancient crown of St. Wenceslas. After 1871 the Czech political leadership was confronted with a dilemma: whether to boycott the parliament and the diets or to join the government majority for concessions in education and economic life. In 1874 the National Party split, with the progressive wing—commonly called the Young Czechs—gaining in popularity among the urban middle class and well-to-do peasants. Rieger found it increasingly difficult to defend his alliance with the big landowners, because it brought no tangible results and obstructed the flow of progressive ideas. The Young Czech deputies insisted on its dissolution and were applauded by their supporters, to whom progress in education, emancipation from clerical influences, and improvement of living standards were more vital than the continued emphasis on unforfeited state right. The Old Czechs lost ground in the 1880s and suffered a total defeat in the parliamentary election of 1891.

Split of the National Party

The most determined opponents of the state-right scheme in 1871 and thereafter were the spokesmen of the German-speaking population of Bohemia and Moravia, later known as the Sudeten Germans, who realized the losses they would suffer with any decentralization of Austria. In the Vienna parliament they cooperated with their kinsmen from the Alpine provinces and helped determine the composition of the cabinets. An alliance between Austria-Hungary and Hohenzollern Germany (1879) increased their sense of belonging to one of Europe's strongest ethnic units, but the German population in Bohemia and Moravia was being reduced in proportion to that of the Czechs. The losses were not spectacular and were largely neutralized by Vienna's reluctance to change the traditional practices of giving preference to German over Czech candidates in civil service and especially in the army. The electoral system for the provincial diet, introduced in 1861, was not changed, although the right to vote in parliamentary elections was extended several times to benefit less-propertied voters. The immediate cause of Rieger's fall was dissatisfaction over concessions he was willing to make to the Germans in 1890. Thereafter, no attempt was made to achieve general agreement on problems of coexistence between the

two ethnic blocs. The largest and richest crown land, in fact, became a trouble spot second only, after 1908, to the southern Slavic provinces.

But the Young Czech leaders were soon caught in the same dilemma that had plagued Rieger. Solemn declarations of adherence to the state-right scheme were followed by bargaining with the prime ministers, who sought potential members of a government coalition and offered tempting concessions, including cabinet posts. Count Kazimierz Badeni, who headed the Austrian cabinet in 1895–97, promised administrative measures that would sanction wider use of Czech in Bohemian civil service and law courts. But he encountered vigorous opposition, organized by German nationalists, in the parliament and lost the emperor's confidence. He resigned, and his successor recognized the futility of trying to adjust the outdated laws in favour of the Czechs.

Decline of the Young Czechs

The changing social and economic stratification also sped the decline of the Young Czechs. They unsuccessfully courted industrial workers, who were more attracted by the Social Democrats and voted for their candidates. Václav Klofáč, a talented journalist, after several years of cooperation with the Young Czechs, founded the National Socialist Party. The peasants, dissatisfied with the increasing influence of big business and the upper middle class, turned away from the Young Czechs after 1890. An agrarian movement soon became the Young Czechs' most dangerous rival, because the peasants predominated in the Czech-speaking areas of Bohemia and Moravia. The Young Czech political program was pervaded by liberal principles, which included anticlericalism; that made it unpalatable to the conservative groups, which favoured close cooperation with the Roman Catholic church and which were stronger in Moravia than in Bohemia. Finally, voters led in Moravia by Adolf Stránský and in both provinces by Tomáš Garrigue Masaryk came to feel that the Young Czechs were not seriously carrying out the progressive ideas included in their program. Parties that developed out of ideological opposition were small when compared with the Agrarians, the Socialists, and the Young Czechs, but their ideas reached the noncommitted voters. The grant of universal manhood suffrage in 1906 greatly improved the chances of parties appealing to the less-propertied voters; instead of helping to consolidate the parliament, however, it caused such differences that the prime ministers, following each other in quick succession, found it increasingly difficult to form a solid majority block. Thus, from the election in 1907 to the outbreak of World War I in 1914, the Chamber of Deputies could easily be bypassed by the court and by the ministries of foreign affairs and war, over which Francis Joseph exercised strong control. The dual monarchy was moving toward more dangerous involvements in international affairs and, finally, toward catastrophe.

Czechoslovakia

THE REPUBLIC TO 1945

Struggle for independence. World War I increased the estrangement between the Germans and the Czechs within the Czech Lands. The Germans lent full support to the war effort of the Central Powers, but among the Czechs the war was unpopular. Opposition to the war, however, was uncoordinated, because Czech political leaders were unable to agree on a program. In December 1914 Masaryk, a representative in the Vienna parliament, left Prague to organize activities that could not be developed at home because of political persecution and the suspension of civil rights. After staying some months in neutral countries, Masaryk moved to London. In 1915 he had been joined in Switzerland by a former student, Edvard Beneš, and by Josef Dürich, a member of the conservative Czech Agrarian Party. Masaryk at first had rather vague notions of the tasks ahead of him, but he eventually opted for a program of political union of the Czechs and Slovaks. A young Slovak astronomer, Milan Rastislav Štefánik, offered his support. Masaryk established contacts with the Czechs and Slovaks living in Allied and neutral countries, especially the United States. In 1916 a Czechoslovak National Council was created under Masaryk's chairmanship. Its members were eager to maintain contacts with the leaders at home in order to avoid disharmony, and an underground organization called the Maffia served as a liaison between them.

At home the influence of the military increased. The press was heavily censored, public meetings were forbidden, and those suspected of disloyalty were imprisoned. Among those arrested were the pro-Russian Young Czech leader Karel Kramář and the economist Alois Rašín. Dissatisfaction among the Czech soldiers on the Eastern Front became more articulate in 1915, and whole units often went over to the Russian side.

Francis Joseph died in November 1916 and was succeeded by Charles I. The new emperor called the parliament to session in Vienna and granted amnesty to political prisoners. Charles's reforms, although in many respects gratifying, called for more intensive activities abroad in order to convince the Allied leaders that partial concessions to the Czechs were inadequate to the problems of postwar reconstruction. The position of the Slovaks was not improving, and the Hungarian government showed no inclination to reorganize the kingdom in accordance with the principle of nationality. Two major events coincided with Charles's new course in home affairs and with his discreet exploration of the chances of a separate peace: the Russian Revolution (March 1917) and the U.S. declaration of war on Germany. In May 1917 Masaryk left London for Russia to speed up organization of a Czechoslovak army. While small units of volunteers had been formed in the Allied countries during the early part of the war, thousands of prisoners of war were now released from Russian camps and trained for service on the Allied side. A Czechoslovak brigade participated in the last Russian offensive and distinguished itself at Zborov (Ukraine) in July 1917. From the United States came moral encouragement, but U.S. President Woodrow Wilson's early statements pertaining to the peace aims were rather hazy. Several weeks after the United States declared war on Austria-Hungary, President Wilson promulgated his celebrated Fourteen Points (January 1918), the 10th of which called for "the freest opportunity of the autonomous development" of the peoples of Austria-Hungary.

Moderate reform under Charles I

After the Russian Revolution, Czechoslovak troops became involved in struggles between the Bolsheviks and the conservative forces for the control of the Siberian railroad. Their achievements, noticed favourably by the Western governments and press, gave the Czechoslovak cause wide publicity and helped its leaders to gain official recognition. Masaryk left Russia for the United States, where, in May 1918, he gained solid support from Czech and Slovak organizations. A declaration favouring political union of the Czechs and Slovaks was issued at Pittsburgh, Pa., on May 31, 1918 (called the Pittsburgh Convention).

Throughout 1918, dealings with the Allies progressed more successfully. Added to the favourable publicity of the Siberian campaigns were increased activities at home to get the struggle for independence endorsed by the Allied governments. A demand for a sovereign state "within the historic frontiers of the Bohemian lands and of Slovakia" was made in Prague at the Epiphany Convention (January) and repeated later with more vigour. In May not only the Czechs but also the Slovaks made statements to which Masaryk and his collaborators could point when pressing for an official recognition. The anti-Austria resolution, adopted at the Congress of Oppressed Nationalities at Rome (April), helped in disarming conservative circles in the Allied countries who opposed a total reorganization of the Danubian region. After several encouraging statements came the recognition by France of the Czechoslovak National Council as the supreme body controlling Czechoslovak national interests; the other Allies soon followed the French initiative. On September 28 Beneš signed a treaty whereby France agreed to support the Czechoslovak program in the postwar peace conference. To preclude a retreat from the earlier Allied declarations, the National Council constituted itself as a provisional government (October 14). Four days later, Masaryk and Beneš issued a declaration of independence simultaneously in Washing-

Moves toward independence

ton, D.C., and Paris. Events were moving rapidly toward total collapse of the Habsburg monarchy. The last attempt to avert it, the manifesto issued by Charles on October 16, brought no positive results. After that, Vienna had no choice but to accept Wilson's terms. The surrender note, signed by Count Gyula Andrássy, the last foreign minister, was accepted as a sanction of the idea of independence. The Prague National Committee proclaimed a republic on October 28, and, two days later, the Slovak National Council at Turčiansky Svätý Martin acceded to the Prague proclamation.

Establishment of Czechoslovakia. Despite all efforts to maintain contacts between the leaders abroad and those at home, the early years of the republic were hindered by differences of opinion and occasional frictions. Masaryk returned to Prague on December 21. Beneš stayed in Paris and was joined by Karel Kramář, who had been prime minister since November. The Slovak leader Štefánik decided to return home but died in an airplane crash in May 1919. Masaryk and Beneš conducted foreign relations, and the leaders of five major parties controlled home affairs.

Of the many tasks facing the new government, negotiations at the postwar peace conference, though complicated by dissensions among the Great Powers, were the least onerous. The frontiers separating Bohemia and Moravia from Germany and Austria were approved, with minor rectifications, in favour of the republic. The Slovak boundary also was satisfactory. The dispute over the Duchy of Teschen strained the relations with Poland; the partition of the duchy in 1920 was opposed by powerful Polish groups, and the Polish senate did not ratify the treaty. The northeastern counties of prewar Hungary (Carpathian Ruthenia) were attached to the new state. The area was inhabited by Slavic peoples, the majority of whom were keenly aware of their kinship with the Ukrainians.

Consolidation of internal affairs proceeded slowly. The winter of 1918–19 was critical. The most urgent task of the new government was to replace the wartime economy with a new system. The network of railroads and highways had to be adjusted to the new shape of the republic, which stretched from the Cheb (Eger) region in western Bohemia to the Carpathians in the east. The new country's first minister of finance, Alois Rašín, saved the Czechoslovak currency from catastrophic inflation, and his death in February 1923, after he was shot by a young revolutionary, was a shock to the new republic.

In the chaotic conditions prevailing in central Europe after the armistice, a parliamentary election appeared to be impossible. The Czech and Slovak leaders agreed on the composition of the National Assembly. The Assembly's main function was the drafting of a constitution. The new, democratic constitution was adopted on Feb. 29, 1920, and was modeled largely on that of the French Third Republic. Supreme power was vested in a bicameral National Assembly. The Chamber of Deputies and the Senate had the right to elect, in a joint session, the president of the republic for a term of seven years. The Cabinet was made responsible to the Assembly. Fundamental rights of the citizens, irrespective of ethnic origin, religion, and social status, were defined generously. Some parties, however, saw a contradiction between the constitutional guarantee of equal rights for all citizens and the intention to create a state of the Czechs and Slovaks.

Opposition from Sudeten Germans

Large segments of the population gave wholehearted support to the republic; the most resolute opposition, however, came from an ethnic minority that soon came to be known as the Sudeten Germans. The age-old antagonism between Germans and Slavs, accentuated during the war, prevented cooperation during the opening stages of the republic. The Germans issued protests against the constitution but participated, nevertheless, in parliamentary and other elections. In 1925 two German parties—the Agrarian and Christian Socialist—joined the government majority, thus breaking a deadlock. Disagreement with the trend toward centralism was the main source of dissatisfaction among the Slovak Populists, a clerical party headed by Andrej Hlinka. Calls for Slovak autonomy were counterbalanced by other parties seeking closer contacts with the corresponding Czech groups; the most significant contribution to that effort was made by the Agrarians under Milan Hodža and by the Social Democrats under Ivan Dérer. The strongest single party in the opening period, the Social Democracy, was split in 1920 by internal struggles; in 1921 its left wing constituted itself as the Czechoslovak section of the Comintern. After the separation of the communists, the Social Democracy yielded primacy to the Agrarians. The Republicans, as the peasant party was called officially, became the backbone of government coalitions until the disruption of the republic; from its ranks came Antonín Švehla (prime minister 1921–29) and his successors.

Political consolidation. Foreign relations were largely determined by wartime agreements. Czechoslovakia adhered loyally to the League of Nations. Treaties with Yugoslavia and Romania gave rise to the Little Entente. France was the only major power that concluded an alliance with Czechoslovakia (January 1924). Relations with Italy, originally friendly, deteriorated after Benito Mussolini's rise to power in 1922. Czech anticlerical feeling precluded negotiation of a concordat with the papacy until 1928, when an agreement was worked out providing for settlement of the most serious disputes between church and state. It was Germany, however, that most strongly influenced the course of Czechoslovak foreign affairs. The relations between the two neighbours improved slightly in 1925 after the Locarno Pact, a series of agreements among the powers of western Europe to guarantee peace. In the milder climate of the late 1920s, a third party, the Social Democrats, joined the German activists. Attempts to change the attitude of the Slovak Populists met with partial success. Reorganization of public administration in 1927, while marking a retreat from rigid centralism, did not go far enough to meet demands for Slovak autonomy. Hlinka and his chief collaborator, Josef Tiso, tenaciously pursued the program of decentralization and only at short intervals supported the Prague government.

Impact of the Great Depression

When the impact of the Great Depression reached Czechoslovakia, soon after 1930, the highly industrialized German-speaking districts were hit more severely than the predominantly agricultural lowlands. The ground was thus prepared for the rise of militant nationalism. Parties supported by middle-class German voters and persisting in opposition to Prague gained in popularity and were encouraged by Adolf Hitler's rise to power in Germany. In October 1933 Konrad Henlein, a supporter of Hitler and head of the politically active Sudeten Turnverband gymnastics society, launched his Sudeten German Home Front. Professing loyalty to the democratic system, he asked for recognition of the German minority as an autonomous body. In 1935 Henlein changed the name of his movement to the Sudeten German Party so as to enable its active participation in the parliamentary election (May 1935). The party captured nearly two-thirds of the Sudeten German vote and became a political force second only to the Czech Agrarians.

Moving toward the abyss. A tense interlude of little more than two years followed the landslide victory of the Sudeten Germans. In December 1935 Masaryk retired from the presidency, and Beneš was elected his successor by an overwhelming majority, including Hlinka's party. A treaty with the Soviet Union in 1935 enhanced the sense of national security. The program of the Communist Party was determined not only by this treaty but also by the general reorientation of the Comintern, which now urged cooperation with antifascist forces in popular fronts. The Czechoslovak communists did not, however, seek cabinet posts. The erection of fortifications along the German frontier modeled on France's Maginot Line was commonly interpreted as an unwritten pledge of the French army to aid Czechoslovakia in the event of an unprovoked attack. Their capture would have given (and later did give) the Germans the key to the French defensive system. In February 1937 Prime Minister Milan Hodža made significant progress toward gaining the cooperation of those segments of the German population that were attached to the principles of democracy. The hope that Czechoslovakia would be able to withstand pressure from Nazi Germany seemed, for a while, to be justified.

But, soon after the death of Masaryk, in September 1937, Hitler embarked on his program of eastward expansion. As early as November 1937, he informed his military chiefs of his intention to move against Austria and Czechoslovakia. After the annexation of Austria in March 1938, the Czechoslovak crisis became acute.

The Czechoslovak leaders divided their energies. Hodža devoted all his talents to a search for a compromise that would satisfy the Sudeten Germans and held long conferences with Henlein's lieutenants. President Beneš, assisted by his foreign minister, Kamil Krofta, maintained contacts with foreign powers. Henlein played his hand so skillfully that the influential circles, especially in London, believed that he was a free agent and not Hitler's stooge. The advocates of "appeasement," then rapidly gaining ground in Britain and France, failed to realize that the Sudeten German negotiators had no intention of compromise and acted on instructions from Berlin. The main task of Henlein's party was to give Hitler a better chance to dislocate the republic without recourse to war. To invalidate critical comments from London and Paris, Beneš consented late in July to the mission of Lord Runciman, whose avowed purpose was to observe and report on conditions within the country.

The crisis culminated in September 1938. Armed with information supplied by Lord Runciman, the British prime minister Neville Chamberlain visited Hitler at Berchtesgaden and Godesberg. Chamberlain assured Hitler that the German objectives could be achieved without fighting. The French consented to Chamberlain's policy, thus abandoning their former commitments. The Soviet Union was under no treaty obligation to assist Czechoslovakia, since the treaty of 1935 was to be operative only if the French would honour their pledges. Thus, the stage was set for a meeting between Hitler, Mussolini, Chamberlain, and Edouard Daladier, at Munich on September 29–30. They agreed on a document enjoining the Prague government to cede to the Third Reich all districts of Bohemia and Moravia with populations that were 50 percent or more German; October 10 was set as the deadline for the transfer of these territories. Although presented as a measure to make Czechoslovakia more homogeneous and viable, the pact and its ruthless implementation sealed the fate of the country.

The Munich agreement

From Munich to the disruption of the republic. Beneš resigned the presidency rather than agree to the German annexation. After several weeks he left Prague, first for London and then for Chicago. The leaders who took over had to face mounting difficulties. The annexations completed according to the Munich timetable were not Czechoslovakia's only territorial losses. Poland obtained the Duchy of Teschen as a reward for its menacing attitude during the Munich crisis. By the Vienna Award (November 2), Hungary was granted large portions of Slovak and Ruthenian territories. By all these amputations Czechoslovakia lost about one-third of its population, and the country was rendered defenseless.

The chances of recuperation were greatly reduced by the rapid growth of centrifugal tendencies. The Slovak Populists, headed since Hlinka's death by Tiso, presented Prague with urgent demands for autonomy, which the government accepted. A similar request came from Carpathian Ruthenia. A cumbersome system composed of three autonomous units (the Czech Lands, Slovakia, and Ruthenia) united by allegiance to the Prague government was introduced late in the fall. On November 30 Emil Hácha was elected president; an Agrarian leader, Rudolf Beran, formed the federal cabinet. Under German pressure the complicated party system was changed drastically. The right and centre parties in the Czech Lands formed the Party of National Unity, while the Socialists organized the Party of Labour. In Slovakia the Populists absorbed all the other political groups. Despite all efforts of the loyal elements, stabilization of political and economic life made little progress. Moreover, the public knew little of the confidential negotiations being conducted in Vienna and Berlin by Tiso's aides, who went along with Hitler's preparation for the final takeover. In early 1939 Tiso's group prepared for the secession of Slovakia, and, on March 14, 1939, the Slovak National Assembly voted for independence. On the following day, Bohemia and Moravia were occupied and proclaimed a protectorate of the Third Reich.

Struggles at home and abroad. The basic laws regulating the status of Bohemia and Moravia were drafted hastily, and many loopholes were left in them to facilitate German intervention. Hitler installed a Reich protector, Konstantin von Neurath, in Prague as his personal representative. The cabinet under President Hácha operated with limited rights and powers. For some two years the protectorate kept the semblance of an autonomous body, but in September 1941 Reinhard Heydrich replaced Neurath as Reich protector and inaugurated a reign of terror. After Heydrich's assassination (May 1942), the Germans virtually took over the country. Hácha stayed on as president, but the cabinet was reconstructed in such a way that it served only as a screen behind which the Germans carried out retaliatory measures and exploited the country's economy for their own purposes. Mass executions, consignment of Czech patriots to concentration camps, and recruitment of young people for work in Germany or behind the front continued until the collapse of the Nazi regime.

German policies

Several months after the proclamation of the protectorate, Beneš moved from Chicago to London to resume his political activities. His position originally was rather awkward, as neither French nor British statesmen wanted to deal with him. But, after the fall of France in the spring of 1940, the British prime minister Winston Churchill granted Beneš recognition; a provisional government, with Jan Šrámek as prime minister, began to function in London. In July 1941 Britain and the Soviet Union granted Beneš and his government-in-exile full recognition. Beneš's main occupation was with diplomacy. He devoted considerable energy to getting the Munich agreement denounced as invalid. While London and Washington were reluctant to make statements that might prejudice the outcome of the future peace conference, Moscow did not hesitate to condemn the past and open bright prospects for cooperation in the war and in the postwar reconstruction. Beneš visited Moscow in December 1943 and signed a treaty of alliance for 20 years, the terms of which far exceeded the pact of 1935. Not only the treaty but also conversations with Klement Gottwald, the leader of the Czechoslovak communists, from then on determined the policies of both the exiles and the underground movement in the protectorate and in Slovakia.

The communist groups gradually took over the leadership from other clandestine organizations. It was of decisive importance that the Red Army penetrated deep into the territory of the republic several months before the Western Allies were able to cross the traditional borderline between Germany and Bohemia. In March 1945 Beneš and other political figures journeyed from London to Moscow to make a final accord with Stalin and Gottwald. A program of postwar reconstruction was worked out under decisive communist influence; Zdeněk Fierlinger became prime minister.

The new government, set up at Košice in Slovakia on April 3, 1945, exercised jurisdiction in the eastern portion of the republic; fighting continued in Moravia and Bohemia until early May. Underground activities, guided by the Czech National Committee, were intensified. On May 5 the people of Prague launched an uprising against the German troops concentrated in central Bohemia and fought them bravely for four days. Their appeals for Allied help were largely ignored. The U.S. general George S. Patton, though sympathetic, did not move from Plzeň, complying with instructions from General Dwight D. Eisenhower. On May 9 the forces of the Soviet marshal Ivan Konev entered Prague. (O.O./Z.A.B.Z.)

POSTWAR CZECHOSLOVAKIA

Provisional regime (1945–48). President Beneš returned to Prague on May 18, 1945, after seven years of exile, with the intention of restoring in Czechoslovakia the liberal democratic regime that he had been forced to abandon in 1938. It would not be an exact replica but an "improved"

Return of Beneš

version adapted to the new circumstances. The problem of minorities was resolved by large-scale expulsions of the Germans and Hungarians from Czechoslovakia. The country was to remain a republic whose president would retain considerable constitutional and executive power; a government based on the electoral performance of the political parties would run the country by means of a professional civil service, while the judiciary would enforce laws passed by parliament (the National Assembly). In his search for improvement, Beneš decided to limit the number of political parties to six; subsequently two additional parties were permitted in Slovakia, but too late for the election in 1946. In the autumn of 1945 Beneš nominated a Provisional National Assembly, which reelected him president and confirmed in office the government that he had appointed in April. Its premier, Fierlinger, was a Social Democrat. The vice premier was Gottwald, and the leaders of all the other political parties also held vice premierships. A general election was to be held to legitimize the provisional regime as well as to test the nation's acceptance of this new order, in compliance with the agreement of the Great Powers at Yalta.

On May 26, 1946, the Communist Party of Czechoslovakia won a great victory in the general election, polling 2,695,293 votes—38.7 percent of the total. The noncommunist parties were not alarmed, however, because in combination they had a decisive majority. Gottwald became premier, and the communists controlled all the key ministries, including interior (Václav Nosek), information (Václav Kopecký), agriculture (Julius Ďuriš), and finance (Julius Dolanský). Foreign affairs were administered by Jan Masaryk, and General Ludvík Svoboda remained minister of defense. Thus the provisional system had been endorsed by an overwhelming majority of the Czechoslovak people; provided the political parties, grouped in a coalition called the National Front, continued to work harmoniously, the provisional regime would be finalized in 1948, when the Constituent Assembly was to produce a constitution and the next general election was to be held.

From the beginning, however, collaboration between the communists and noncommunists was difficult, and it only became worse. While all parties agreed that the program of postwar economic recovery should continue, and while a two-year plan was launched to carry it out, they began to differ as to the means to be employed. The noncommunists wanted no further nationalizations or land confiscations, no special taxes, raises in pay for the civil service, and, above all, economic aid from the United States by way of the Marshall Plan. When in 1947 the idea of Marshall Plan aid had to be abandoned because of pressure from the Soviet Union, the Czechoslovak coalition partners realized that long-term cooperation was impossible, and each party thought of how to resolve the conflict in its own favour. Gottwald and the communists, while mistrusting their coalition partners, still thought in purely Czechoslovak terms when they announced their strategy: gain an absolute majority (51 percent) in the next election. They organized their party in such a way as to achieve this aim and more: they wanted to be able to mobilize their membership at any given time to exert pressure within the system. Their opponents were disunited, with no common tactics or organization; they had only a common desire to defeat the communists within the system. After blocking communist policies within the government throughout 1947, they were eagerly waiting for the coming election to defeat the communists decisively.

Marshall Plan aid

The crisis between the two factions came over the question of who was to control the police during the elections. In February 1948 a majority at a cabinet meeting adopted a resolution ordering the minister of the interior (a communist) to stop the practice of packing the police force with communists. The minister ignored the instruction and was supported by Gottwald. On February 20 most of the noncommunist ministers resigned, hoping to force Gottwald to resign as well. He did not. Instead, communists seized the ministries held by resigning ministers and the headquarters of the parties now in opposition. Mass demonstrations of communist-led workers took place, and columns of workers armed with rifles paraded through the streets of Prague. In the capital and in the provinces, "action committees" of communists and of men and women nominated by communists were set up, and authorities were ordered to cooperate with them.

President Beneš yielded. On February 25 a new government was formed in which the communists held the key posts, left-wing Social Democrats were well represented, and the other parties were nominally represented by individual members chosen not by the parties themselves but by the communists. The Provisional National Assembly overwhelmingly endorsed the new government and its program.

Most of the noncommunist political leaders fled the country; thousands of intellectuals and managers also escaped, in some cases shooting their way out; many ordinary people also went to the West to avoid living under communism. On March 10 the body of Jan Masaryk was found beneath a window of the Foreign Ministry.

Death of Jan Masaryk

Overnight the Communist Party had come to be the only organized body left to run the country. More than a million noncommunists joined it to help Gottwald, who, overwhelmed by the power he so suddenly possessed, continued to cherish a dream of the Czechoslovak way to communism.

People's democracy. As had happened in the past and was to happen in the future, the Czechs and Slovaks became so self-centred after momentous events that they forgot the world around them. Gottwald also chose to ignore foreign affairs, even the expanding Soviet hegemony in eastern Europe, and plunged into domestic reforms. Industry was now completely nationalized, and the confiscation of agricultural land was further extended. A new constitution was promulgated on May 9; since it was based on the Soviet model, Beneš refused to sanction it and resigned (he died three months later). Under a new electoral law and with a single list of candidates, a general election was held on May 30, and the new National Assembly elected Gottwald president. His friend Antonín Zápotocký succeeded him as premier, while the Communist Party itself was headed by Rudolf Slánský. Throughout the autumn of 1948, the National Assembly, now a pliant tool of the party, passed reform laws, preparing the administrative reorganization and drawing up a five-year economic plan. But it all proved to be in vain. Gottwald went on a holiday to the Crimea, where the Soviet premier Joseph Stalin told him what would happen in Czechoslovakia.

Stalin's will subsequently was imposed on the country. Czechoslovakia had to adopt the Soviet model of government: the Communist Party substituted itself for the state. Gottwald and his communists seemed incapable of running the country along Soviet lines and rooting out subversion. Josip Broz Tito's break with Stalin in Yugoslavia prompted Moscow to tighten discipline within the socialist camp; in autumn 1949 Soviet advisers were sent to Czechoslovakia.

Gottwald had initiated a campaign against the Christian, especially the Roman Catholic, church in June, interning Catholic archbishops and bishops and isolating the church from Rome. Monasteries and religious orders were dissolved, and a state office for church affairs was set up to bring churches under communist control. Soviet security advisers helped prepare the trials of the clergy who refused to cooperate with the communist authorities, and an effort was made to organize a group of collaborationist clergy.

A series of purges began in 1950, with noncommunists charged with various antistate activities. In June, Milada Horáková, a former member of the National Assembly, and other politicians from the right to the left were tried for espionage, and several, including Horáková, were sentenced to death. Gottwald also was under pressure to uncover ideological opponents in his own party, whose leaders the Soviet advisers now began to scrutinize. Evidence of "nationalistic deviationism" and "Titoism" was found, and a purge of the Communist Party of Czechoslovakia followed.

In 1950 Vladimír Clementis, the foreign minister, was dismissed from office, as were Gustav Husák, the Slovak regional premier, and several other Slovaks; all were accused of bourgeois nationalism. In February 1951

Party purge

Clementis, Husák, and several others were arrested, and in December 1952 Clementis was executed. Ten other high party officials, one of whom was the first secretary, Rudolf Slánský, also were killed. The 10—most of whom, including Slánský, were Jewish—were accused of leading an antistate conspiracy. Altogether, some 180 politicians were killed in these purges, while thousands were held in prisons and concentration camps.

In March 1953, a few days after Stalin's death, Gottwald unexpectedly died. Antonín Zápotocký succeeded Gottwald as president, while Viliám Široký became premier. Both wanted to return to a less repressive way of government, but the widespread rioting that followed a monetary reform (which effectively deprived the farmers and better-paid workers of all their savings) in May 1953 gave the diehard faction, led by Antonín Novotný, the new first secretary, an excuse to check Zápotocký's and Široký's initiative. Novotný formally became first secretary of the party in September 1953, and in 1954 he and his faction appealed to the Soviet Union to stop the reform attempts. The Czechoslovak leadership was invited to Moscow, and President Zápotocký was told to adhere to "collective leadership," which in practice meant abandoning power to Novotný. Events in Poland and Hungary in 1956 further justified Novotný's caution in the eyes of the Soviet authorities, and in 1957, when Zápotocký died, Novotný was able once again to combine the party secretaryship with the presidency. His faction—mostly mediocre apparatchiks—became supreme and remained so until 1968.

Novotný kept Stalinism alive. Show trials continued until 1955, after which administrative sanctions began to be employed. Terror and administrative sanctions, however, could not solve problems, either in the economy or in cultural life, and the bullying of the Novotný faction resulted only in hopeless "distortions." In 1958 an industrial reform was carried through, but it failed to resolve long-term problems. Under the first three five-year plans, industrial production was much increased, but by the early 1960s stagnation had set in and production began to fall. Production costs were high, fuel supplies were short, the quality of goods was poor, and absenteeism was widespread. In agriculture the situation was worse: collectivized agriculture produced less in 1960 than had been produced in the prewar years. The educational system was reorganized on the Soviet model, and in the arts Socialist Realism became the norm; both were stultified.

In July 1960, at a conference of the Communist Party of Czechoslovakia, a new constitution was approved, becoming law in the same month. It laid down that "education and all cultural policy are carried out in the spirit of scientific Marxism-Leninism," and it limited personal property to "consumer goods" and "savings acquired through work." The country's official title of "people's republic" was changed to "socialist republic."

Reform movement. After Novotný had proclaimed his achievements in the new constitution, he experienced nothing but setbacks. His Third Five-Year Plan had to be canceled in the summer of 1962. The agricultural situation did not improve, and the young generation, raised under the communist regime, became critical of the low standard of living that the system seemed to generate. Novotný, whether he liked it or not, was forced into reforms proposed by new members of the Central Committee.

New economic principles

In September 1964 the government accepted a new set of economic principles put forward by the reformers, prominent among whom was Ota Šik, a professor of economics. The main principle was to move from total planning and centralization to a mixed economy, with managers of enterprises having more control over their management and the efficiency of each enterprise being measured by its "profitability" in terms of the labour and capital invested. Wholesale prices were to be reformed, and in 1966 it was decided to do this in two stages, in 1967 and 1968. Reform in agriculture was approached in 1966, with a cutback in central planning and introduction of marketing principles. To attract Western currency, tourism was to be encouraged, and from June 1964 visitors were offered double the old tourist rate of exchange. Novotný, however, refused to seek credit from the West, and this nullified many reform measures. In agriculture he was cautious about a new plan for cooperatives to be amalgamated into huge agricultural enterprises, and as a consequence production continued to stagnate. Novotný's timid reforms thus satisfied no one, resolved no serious problems, and brought into existence pressure groups (the "economists") within the party leadership.

Still, the pressure groups would not have been able to overturn him had he not stirred up Slovak nationalism. In 1960 he agreed to the rehabilitation of the Slovaks purged in the 1950s. The new constitution, however, restricted Slovak autonomy further. By 1963, new leaders had moved into power in Slovakia; Karol Bacílek, who was compromised by the purges in the 1950s, was replaced as first secretary of the party in Slovakia by Alexander Dubček. When the rehabilitated Slovaks, among whom was Gustav Husák, began to clamour for a federal solution to their problem, Novotný thought of another repression in Slovakia. But the new men, dissatisfied with the loss of autonomy in 1960, turned against him, and they were largely responsible for his downfall. Before this could be achieved, Novotný blundered in the field of international affairs. In October 1964, when the Soviet leaders removed Nikita Khrushchev from power, Novotný protested. Thus, when it came time for his own deposition in 1968, he had no one to appeal to as he had had in 1954 against Zápotocký.

Curiously, the immediate cause of his downfall was unrest in the cultural sphere. Students had been restless throughout the 1960s, and their traditional procession, the Majales, in 1966 was turned into a riot against the regime. Then in 1967, dissatisfied with the conditions in their colleges, they went into the streets and clashed with the police. In the end, the minister of the interior had to apologize to them (December 15) for police brutality. The intelligentsia in general was more insistently questioning why no institutionalized criticism and no official opposition were permitted.

Student riots

It was the writers (who since 1962 had been challenging censorship and the ideology that supported it), however, that were the most immediate cause of Novotný's fall. At their fourth congress, in 1967, many writers refused to conform to the standards of intellectual discipline set by Novotný. He was still able to answer back with sanctions: Jan Beneš was sent to prison for antistate propaganda; Ludvík Vaculík, Antonín J. Liehm, and Ivan Klíma were expelled from the party; and Jan Procházka was dismissed from the Central Committee, of which he was a candidate member. This repression so disturbed the opponents of Novotný that they provoked a crisis in the leadership.

During the session of the Central Committee in October 1967, an open clash occurred between Novotný and the Slovaks. Novotný hinted that Alexander Dubček and the other Slovak opposition were tainted with bourgeois nationalism, and he thus sealed his fate as a leader. In addition, he spoke to his generals of a *coup de palais* and invited Leonid Brezhnev, first secretary of the Communist Party of the Soviet Union, to Prague to help him. Brezhnev apparently refused to be involved, and Novotný, now deserted, had to face a hostile session in December. After Šik's demand that the presidency be separated from the party office, Novotný offered his resignation as first secretary. This was accepted at the next session, and in January 1968 Novotný himself recommended as his successor his Slovak opponent Dubček, who was elected unanimously.

The Prague Spring of 1968. Although Alexander Dubček subsequently became the chief reformer, he was not particularly qualified for this role. He was a young Slovak who made his way into politics through the party apparat. People did not expect much from him, and for a month nothing seems to have happened. As the representative of a new generation, Dubček must have felt frustrated with the Novotný type of apparatchiks, and, though he was in power, he did not control the apparat. That is probably why he decided on an experiment rather than the time-honoured purge techniques. His way of getting rid of the old guard was to subject them to the pressure of public opinion. Once he had made this vital decision, many reforms followed. By April the apparat was

Dubček and the apparat

Dubček's. Several diehards preferred suicide to disgrace, but Novotný and many others resigned only after a hard struggle. There was a new premier, Oldřich Černík, and Šik and Husák became vice premiers in charge of reforms in, respectively, the economy and Slovakia. Czechoslovakia also had a new president (from March 30), Ludvík Svoboda, who had been purged in the 1950s and had lived in retirement since then. The Ministry of the Interior was under the control of another purge victim, Josef Pavel. The newly elected Presidium of the Communist Party consisted largely of newcomers, and the Action Program was compiled by young party intellectuals.

The Action Program, adopted by the Central Committee on April 5, embodied the reform ideas of the several years preceding, and it accepted the connection between economic and political reform. Among its most important points were a new autonomy for the Slovaks (federation); industrial and agricultural reforms, so long overdue; a revised constitution that would guarantee civil rights and liberties; and complete rehabilitation of all citizens whose rights had been infringed in the past. The program also envisaged a strict division of powers: the National Assembly, not the Communist Party, would be in control of the government, which in turn would become a real executive body and not a party body; courts were to become independent and act as arbiters between the legislative and executive branches. The Communist Party would have to justify its leading role by competing freely for supremacy with other forces in elections. This democratization of life in the country also would extend to the party, in which all offices would be elective. Dubček claimed that he was offering "socialism with a human face."

The effect that all these happenings had on the Czechoslovak public was unprecedented and quite unexpected. With freedom of the press reestablished, there was a revival of interest in alternative forms of political organization. There were even efforts to reestablish the Social Democratic Party, fused forcibly with the Communist Party in 1948. With the collapse of the official communist youth movement, youth clubs and the Boy Scout movement were resurrected. The Christian churches became active as unexpectedly as did many long-forgotten societies, national minority associations, and human-rights movements.

The "Two Thousand Words"

On June 27 there appeared in *Literární listy* ("Literary Gazette") a document written by Ludvík Vaculík and signed by a large number of people representing all walks of Czechoslovak life. This was the "Two Thousand Words," urging even more rapid progress to real democracy. Dubček—not to mention the Soviet Union and the other Warsaw Pact allies (with the exception of Romania)—became apprehensive, but, though shocked by the proclamation, Dubček remained convinced that he could control the transformation of Czechoslovakia. The Soviet Union, however, began to take a different view. The Czechs and Slovaks failed to comprehend the hostility of the reaction to the "Two Thousand Words," particularly by the Soviet Union, Poland, and East Germany. Dubček declined an invitation to participate in a special meeting of the Warsaw Pact powers, which on July 15 sent him a letter saying that his country was on the verge of counterrevolution and that they considered it their duty to protect it. To the last, Dubček remained confident that he could talk himself out of any difficulties with his communist neighbours. He accepted an invitation by Brezhnev to a conference at Čierná-nad-Tisou (a small town in Slovakia), where the Soviet Politburo and the Czechoslovak leaders tried to resolve their problems. On August 3, representatives of the Soviet, East German, Polish, Bulgarian, Hungarian, and Czechoslovak Communist parties met at Bratislava; the communiqué issued after the meeting, while loosely written, gave the impression that pressure would be eased on Czechoslovakia in return for somewhat tighter control over the press.

On the evening of August 20, however, Soviet, East German, Polish, Hungarian, and Bulgarian armed forces invaded the country and occupied it with little opposition. Politically, the invasion was a catastrophe. The Soviet authorities seized Dubček, Černík, and several other leaders and took them to Moscow but failed to produce alternative party and state leaders acceptable to the people. The population reacted against the invasion with passive resistance and improvisation (*e.g.*, road signs were removed so that the invading troops would get lost). Communications were disrupted, supplies were held up, and the country was almost leaderless, but life went on as if the occupation forces were not there. Even the scheduled 14th Communist Party Congress took place on August 22 and elected a pro-Dubček Central Committee and Presidium—the very thing the invasion had been timed to prevent. The National Assembly (declaring its loyalty to Dubček) continued its plenary sessions. On August 23 President Svoboda, accompanied by Husák, left for Moscow to negotiate a solution. The negotiations were concluded on August 27, and Svoboda, bringing with him Dubček, Černík, and Smrkovský, returned to Prague to tell the Czechs and Slovaks what price they would have to pay for their socialism with a human face: Soviet troops were going to stay in Czechoslovakia, and the leaders had agreed to tighter controls over political and cultural activities.

The presence of Soviet troops helped the hardliners defeat Dubček and the reformers. First of all, the 14th party congress was declared invalid, as required by the Moscow Protocol agreed upon on August 26. Thus, the hardliners remained in positions of power and, by using Soviet pressure and divisions among the reformers, ultimately achieved their victory. In the meantime Czechoslovakia became a federal republic, the Czech Lands (Bohemia and Moravia) and Slovakia becoming the Czech Socialist Republic and the Slovak Socialist Republic, respectively, with national parliaments and governments. The Czech and Slovak people, however, were more impressed by the suicide of Jan Palach—a student who in January 1969 set himself afire in protest against infringements of national independence—than by Dubček's declarations that the revival movement was going on as before the invasion. Gradually Dubček either dismissed his friends and allies or forced them to resign, until he found himself isolated.

This slow rise of the hardliners and of the "realists" (among whom was Husák) culminated on April 17, 1969, when Dubček was removed as first secretary after anti-Soviet rioting in Czechoslovakia. Dubček was replaced by Husák, who promptly declared the Dubček experiments to be finished and proposed a process that he called "normalization."

Husák's policies. Husák's modest policy of normalization included the dual aim of ending political experiments and concentrating on economic progress. He patiently tried to persuade Soviet leaders that Czechoslovakia was an orthodox member of the Warsaw Pact. He had the constitution amended to embody the newly proclaimed principle of proletarian internationalism and in 1971 went as far as to repudiate the Prague Spring, declaring that "in 1968 socialism was in danger in Czechoslovakia, and the armed intervention helped to save it." His most cherished aim was to turn the federal arrangements, which came into force on Jan. 1, 1969, into a reality and then concentrate on economic problems. In fact, the implementation of federalism had helped him to get rid of many hardliners and supplant them with his own people. In 1970 Oldřich Černík was finally forced to resign the premiership and was succeeded by Husák's Czech rival, Lubomír Štrougal. In 1975, when President Svoboda retired because of ill health, Husák once again fused the two most important offices in Czechoslovakia and became president himself, with full Soviet approval.

Federalism

Economic problems. After the purge of 1969–71, Husák concentrated almost exclusively on the economy. In the short term, Czechoslovakia did not suffer significantly, even from the disruption caused by the military occupation in 1968. Husák, however, did not permit the industrial and agricultural reforms to be applied and so failed to cure the long-term economic problems. The achievements of the next several five-year economic periods were modest, and by the early 1980s Czechoslovakia was experiencing a serious economic downturn caused by a decline in markets for its products, burdensome terms of trade with several of its supplier nations, and a surplus of outdated machinery and technology.

Political dissidence. In the years that he was in power, Husák succeeded in consolidating public life without the bloodletting of his predecessors, but his party purges damaged Czechoslovak cultural and scientific life, since positions in these two areas depended on membership in the party. Many writers, composers, journalists, and historians as well as scientists found themselves unemployed and forced to accept menial jobs to earn a living.

Many of these disappointed communist intellectuals tried to continue the political struggle against Husák, but he eliminated them by proving in court that they had committed criminal acts in pursuance of political objectives. Though these trials could not be compared to the Stalinist show trials, they kept discontent among the intellectuals simmering, even if the mass of the population was indifferent. Intellectual discontent erupted again in January 1977, when a group of intellectuals signed a petition, known as Charter 77, in which they aired their grievances against the Husák regime. Many intellectuals and activists who signed the petition subsequently were arrested and detained, but their efforts continued throughout the following decade. (J.F.N.B./Z.A.B.Z.)

The collapse of communism and dissolution of the federation. The persecuted Charter 77 group played a leading role in the popular upheaval (known as the Velvet Revolution) that ended communist control of Czechoslovakia in late 1989. On November 17 the authorities allowed a demonstration commemorating the 50th anniversary of the brutal suppression of a student demonstration in German-occupied Prague. The recurrence of police brutality at the anniversary observance set off a protest movement that gained particular strength in the country's industrial centres. Prodemocracy demonstrations and strikes continued nationwide under the leadership of Civic Forum, an opposition group for which the dissident playwright and Charter 77 signer Václav Havel served as chief spokesman. It was Havel who in late December became Czechoslovakia's first noncommunist president in more than 40 years following the resignation of the communist government and his election to the office by a parliament still dominated by communist deputies. In addition, the former party leader Alexander Dubček returned to political life as the new speaker of parliament. In June 1990, in the first free elections held in Czechoslovakia since 1946, the Civic Forum movement and the Slovak counterpart won decisive majorities in both houses of parliament.

Civic Forum

The new government undertook the multifarious tasks of transition, including privatizing businesses, revamping foreign policy, and writing a new constitution. The last Soviet troops were withdrawn from Czechoslovakia in June 1991, and the Warsaw Pact was disbanded the following month, thus completing Czechoslovakia's separation from the Soviet sphere. The drafting of a new constitution was hindered by differences between parties, Czech-Slovak tensions, and power struggles.

As separatism became a momentous issue in 1991–92, the Czechoslovak federation began to appear fragile; the Civic Forum disintegrated. Parliamentary elections in June 1992 gave the Czech premiership to Václav Klaus, an economic reformer, while the Slovak premiership went to Vladimir Mečiar, a vocal Slovak separatist. Though they headed the two strongest political parties on both the republic and federal levels, they were supported by only about one-third of the electorate. In addition, no suitable candidate for the federal presidency emerged. After Havel's resignation on July 20, Czechoslovakia lacked a visible symbol as well as a convincing advocate. Thus, the assumption was readily made, at least in political circles, that the state would have to be divided. Negotiations between the two republics took place in an atmosphere of peace and cooperation, though there was little evidence of public enthusiasm. By late November, members of the National Assembly had voted Czechoslovakia out of existence and themselves out of their jobs. Both republics promulgated new constitutions, and at midnight on December 31, Czechoslovakia was formally dissolved. (Z.A.B.Z.)

SLOVAKIA

MODERN STATES OF THE REGION

Czech Republic

The landlocked Czech Republic (Czech: Česká Republika) comprises the historic lands of Bohemia and Moravia (collectively often called the Czech Lands) and the southwestern corner of Silesia. The modern Czech nation was inaugurated on Jan. 1, 1993, when the union with Slovakia was dissolved; the Communist Party controlled the federal government from 1948 to 1989. The Czech Republic is bordered by Poland to the north and northeast, Slovakia to the east, Austria to the south, and Germany to the west and northwest. It has an area of 30,450 square miles (78,864 square kilometres). The capital is Prague (Praha).

THE LAND

Relief. The Bohemian Massif occupies most of the Czech Republic. It consists of a large, elevated basin (the Bohemian Plateau) encircled by six major mountain groups. In the southwest, the Šumava Mountains include the Bohemian Forest. In the west are the Berounka River highlands. The Ore Mountains (Czech: Krušné hory; German: Erzgebirge) in the northwest border Germany and contain the country's lowest point (384 feet [117 metres]), where the Elbe (Labe) River breaches this range. The Sudeten Mountains in the northeast form most of the frontier with Poland west of Ostrava and contain the country's highest elevation—5,256 feet (1,602 metres) at Mount Sněžka in the Krkonoše (Giant) Mountains. Farther east is the Oder (Odra) River lowland, a small fringe along the Polish border. Finally, south of the Bohemian Plateau is the Bohemian-Moravian Highlands, which includes the spectacular Moravian Karst.

In the east the Outer Carpathian Depressions, known to geographers as the Moravian-Silesian Beskids, include the valleys of the upper Oder and Morava rivers and the headstreams of the Dyje. Along the Czech-Slovak border rise the Little Carpathian (Czech: Bílé Karpaty) and Javorníky ranges, the westernmost of the Western Carpathian Mountains that dominate Slovakia.

Drainage and soils. The Czech Republic lies in the headwater area of the central European watershed. The Elbe River rises near the Czech-Polish border and sweeps southwestward across Bohemia, receiving the Jizera, the Vltava, and Ohře rivers before flowing northward into Germany. The Morava River, flowing south toward the Danube (Dunaj) River, drains most of Moravia in the east. The Oder River rises in the northeastern Czech Republic and flows northward into Poland. There also are many smaller rivers of little economic importance. The greatest flows generally occur in spring and the lowest in summer. The country is rich in mineral springs, and groundwater reserves are extensively used.

The soil profile consists of rich black chernozems and good-quality brown soils in the drier and lower areas, podzols in the wet districts, and stony mountain soils at high elevations. Alluvial soils occur in the river basins, and heavy clay soils are found in the eastern ridges.

Climate. The Czech climate is mixed. Continental influences are marked by large fluctuations in both temperature and precipitation, while moderating oceanic influences diminish from west to east. In general, temperatures decrease with increasing altitude but are relatively uniform across the country at lower elevations. The mean annual temperature at Cheb in the extreme west is 45° F (7° Temperatures

C) and rises to only 48° F (9° C) at Brno in southern Moravia. High temperatures can reach 91° F (33° C) in Prague during July, and low temperatures may drop to 1° F (−17° C) in Cheb during February. The growing season is about 200 days in the south but less than half that in the mountains.

Annual precipitation ranges from 18 inches (450 millimetres) in the central Bohemian basins to more than 60 inches on windward slopes of the Krkonoše Mountains of the north. Maximum precipitation falls during July, while the minimum occurs in February. There are no recognizable climatic zones but rather a succession of small and varied districts; climate thus follows the topography in contributing to the diversity of the natural environment.

Plant and animal life. Although large areas of the original forest cover have been cleared for cultivation and for timber, woodlands remain a characteristic feature of the Czech landscape. Oak, beech, and spruce dominate the forest zones in ascending order of altitude. In the highest elevations can be found taiga and tundra vegetation characteristic of more northerly or more elevated regions elsewhere in Europe. The timberline runs at about 4,500 feet above sea level. At these higher elevations, as in the Krkonoše Mountains, the tree cover below the timberline consists of little more than dwarf pine. The Alpine zone supports grasses and low-growing bushes.

The country's wildlife is extensive and varied. Large mammals include bears, wolves, lynx, and wildcats (*Felis sylvestris*). Smaller mammals such as marmots, otters, martens, and minks also inhabit the forests and wetlands. Game birds, especially pheasants, partridges, wild geese, and ducks, are common. Rarer species such as eagles, vultures, ospreys, storks, eagle owls, bustards, and capercaillies generally are protected.

The preservation of the natural heritage is an important goal of the Czech government. Rare or endangered species such as the mouflon (a mountain sheep) are bred in game reserves, and nature reserves have been created to preserve especially important landscapes, notably the Šumava Forest, Moravian Karst, and Jizera Mountains. Tourists are given controlled access to the reserve areas. Krkonoše National Park, established in 1963, protects glacial and Alpine landscapes and vegetation and some relict boreal-Arctic species, such as the Alpine shrew (*Sorex alpinus*); it is extensively developed as a ski resort, however.

Settlement patterns. Industrialization and urbanization have changed the face of the Czech traditional regions, although Bohemia and to a lesser extent Moravia are still recognizable entities, reflecting different national and cultural heritages. Local traditions are preserved in southern Bohemia and southeastern Moravia in cuisine and in the styles of folk costumes worn on special occasions. Traditional wooden architecture is a distinctive feature of some rural areas.

The country has a high density of settlement, with communities lying, on average, only a few miles apart. A notable feature is the low density in some frontier areas, partly reflecting the induced emigration of minorities after World War II. Rural settlements are characteristically compact, but in the mountainous regions, colonized during the 13th and 14th centuries, villages straggling along narrow valleys are common. The collectivization of farmland that took place in the decades following World War II resulted in a pattern of large, regularly shaped fields, replacing the centuries-old division of land into small, irregular, privately owned plots.

Urbanization

Urbanization in the Czech Republic is not particularly high for an industrialized country. Even the smallest urban centres, however, usually contain some manufacturing industry. Prague, the national capital, historically occupies a predominant role. Brno is the chief city of Moravia. The other large cities are Ostrava, the leading coal-mining and steel centre; and Plzeň, with old, established engineering and brewing industries.

New towns were founded both before and after World War II. Notable among prewar settlements is the Morava valley town of Zlín, founded in 1923. The towns of Havířov in the east and Ostrov, near Karlovy Vary, in the west have been built since World War II, and all have substantial populations.

THE PEOPLE

Ethnic groups. Czechs make up roughly 95 percent of the population, although the Moravians consider themselves to be a distinct group within this majority. A significant Slovak minority remains from the federal period. A small Polish population exists in northeastern Moravia, and some Germans still live in northwestern Bohemia. The Gypsies (Roma) constitute a small, distinct minority.

Languages. The majority of the population speak Czech as their first language, while Slovak is the first language of the largest minority. These mutually intelligible languages belong to the West Slavic language group, which uses the Roman rather than the Cyrillic alphabet. Czech as a literary language dates to the late 13th century. Hungarian, Polish, German, Ukrainian, Romany, and Russian are among the other languages spoken in the republic.

Religions. During the communist era, no official statis-

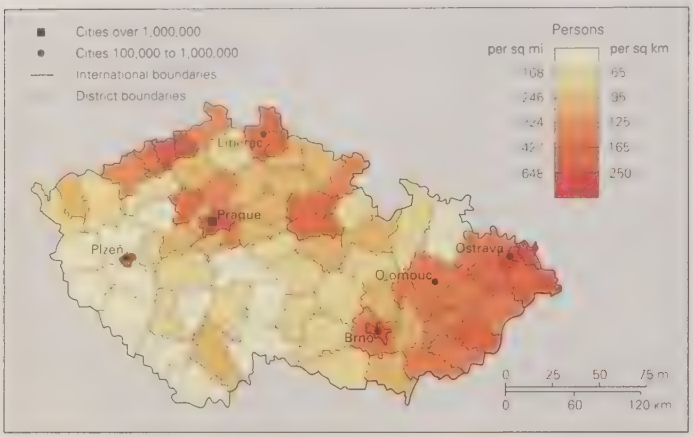
Ski resort in the Krkonoše (Giant) Mountains, a range in the Sudeten Mountains in northeastern Bohemia, Czech Republic.

tics were kept on religion, though the activities of the churches were financed by the government following the nationalization of all church property by 1949. Atheism was the official government religious philosophy, and the churches' role was largely restricted to religious rites. Following restoration of religious freedom in 1989, it was estimated that some three-fifths of Czechs professed a religious affiliation. A visit to Czechoslovakia by Pope John Paul II in April 1990 celebrated the resurgence of Roman Catholicism, which counted nearly two-fifths of the population as adherents. There are also Eastern Orthodox congregations and various small Protestant sects.



Population density of the Czech Republic.

Demographic trends. In the past, population growth was slowed by emigration to the urban centres of Austria-Hungary and overseas, especially to the United States. During the modern federal period, Czechoslovakia's rather slow rate of growth was attributable in part to the changes in lifestyle associated with urbanization and with the increased employment of women outside the home. With relatively low birth rates and a prolongation of the average life span, the average age of the population is increasing. A high percentage of the inhabitants of central and eastern Bohemia are elderly. Partition in 1993 exerted new and unpredictable demographic pressures, as citizens of the dissolving country—many of them living outside their home region—selected the new republic to which they would belong. (M.Bl./R.H.O./F.W.C.)

Aging population

THE ECONOMY

In many respects, the partition of Czechoslovakia in 1993 represented for the emergent Czech Republic an economizing measure far more effective than any that domestic government policy could hope to accomplish. While the Czech Republic and Slovakia officially shared the status of successors to the federal state, long-standing inequities in economic development gave the Czechs a decided advantage at independence. Rigid compartmentalization under the Czechoslovak planned economy made Slovakia, with its mineral resources and hydroelectric potential, a major producer of armaments for the former communist nations of eastern Europe. The economy of the Czech Republic, on the other hand, was relatively diversified and stable, reflecting both a more amenable geography and the historic predominance of Czechs in the federal administration. Similarly, the transition to a market economy initiated after the so-called Velvet Revolution of 1989 lagged behind in Slovakia. Irrespective of deeper societal factors, these imbalances predisposed Czechs to favour partition, while the Slovaks were divided in their view of the federal partnership as either an obscuring shadow or a sheltering wing.

Once the political breach came to seem inevitable, the unprecedented requirements for dividing the economy assumed a somewhat tentative order of priority. At partition, the federal monetary system remained essentially intact, each country identifying its currency supply by means of applied stamps. The rapid economic divergence of the two republics, however, ended the arrangement after only one month, and separate currencies were inaugurated.

The historic imbalance in government assets between the two territories made fair apportionment after partition a difficult goal. This was particularly true in the case of military installations and equipment, of which the Czech Republic held the great majority. The bulk of Slovakia's military-industrial component, by contrast, consisted in its armament manufacture, which had declined precipitously with the collapse of communism. Despite its inherent advantages, the Czech economy faced independence at a time when recent emergence from the Soviet bloc, coupled with the rigours of privatization, had caused a dramatic short-term increase in prices and unemployment. The government instituted a value-added tax in its effort to align the economy with Western markets. (F.W.C.)

Resources. Although reserves are limited, bituminous, anthracite, and brown coals are produced in significant quantities. Most of the bituminous coal is derived from the Ostrava-Karviná coalfield, though it is also mined near Kladno, in the Plzeň basin, near Trutnov, and near Brno. A high proportion of the bituminous coal is of coking quality. Production of brown coal increased rapidly up to the mid-20th century and has remained fairly static since then, although demand for it was maintained by the delay in conversion to gas heating; open-pit mining methods are used. The main mining areas are in the extreme west around Chomutov, Most, Teplice, and Sokolov. The brown coal is used in thermal power stations, as fuel in the home, and as raw material in the chemical industry. Small quantities of petroleum and natural gas are produced near Hodonín on the Slovak border. Pipelines import Russian oil and natural gas, the latter supplementing existing coal gas supplies. Plans for reducing dependence on Russian oil sources include the building of a pipeline to carry oil from Trieste to the Czech Republic. There has been a slight drop in energy use, and brown coal output also has suffered some decline. Nuclear power plants located in Dukovany and Temelín, as well as nuclear power from Slovakia, have reduced the country's dependence on coal.

Coal

The Czech Republic has a limited endowment of metallic ores. The area between Prague and Plzeň has been important for its iron deposits. Lead and zinc ores are mined near Kutná Hora and Příbram in Bohemia and in the Hrubý Jeseník Mountains in the northeast. Uranium is mined near Příbram and around Hamr in northern Bohemia. There is a significant deposit of gold at Mokrsko, in central Bohemia south of Prague. The Ore Mountains of Bohemia yield small quantities of tin. Other mineral resources include graphite near České Budějovice and kaolin near Plzeň and Karlovy Vary.

Agriculture and forestry. Czech agriculture is among the most advanced in eastern Europe, with better-than-average yields. The country does not suffer from a shortage of agricultural land, but such land in the Czech Republic is used far less efficiently than that in western Europe. Economists have predicted that removal of agriculture from central government planning would render it more responsive to consumer demand and business productivity. Gradual restoration of land to previous owners from whom it had been confiscated after World War II was expected to result in the reestablishment of private farming in some cases and in the continuation of some cooperative ventures.

Cereals lead in total agricultural production, with wheat, barley, rye, oats, and potatoes as the most important crops. Pigs, cattle, sheep, and poultry are the dominant livestock.

Reforestation efforts of the early 1980s were offset by the effects of acid rain, which prompted cutting beyond the projected rate. By 1989 nearly three-fifths of the republic's forests had been destroyed or seriously damaged.

Industry. Although overall industry in the Czech Republic can be characterized as obsolete, some sectors, notably electronics, are modern and efficient and could be competitive in international markets, given an infusion of investment and management skill. Engineering is the largest branch of industry. Also important is food processing, followed by the chemical, rubber, cement, and glass industries, ferrous metallurgy, and fuel mining and processing. The Czech iron and steel industries have traditionally been among the largest in eastern Europe

Iron and steel

and are based mainly on imported ores. Steel production is centred in the Ostrava area (in Moravia), with lesser amounts produced at Kladno, Plzeň, and Chomutov (all in Bohemia). The heavy manufacturing sector produces automobiles, trucks, tractors, buses, airplanes, motorcycles, and diesel and electric locomotives and rail cars.

Tourism. Prior to 1989 the tourism industry catered largely to eastern Europeans. Following democratization, an increasing proportion of tourists came from western Europe and the United States, and earnings from tourism increased dramatically throughout the 1990s. Principal attractions include historic Prague, numerous spas and mineral springs, winter resorts, and various cultural festivals.

Finance. On the day of partition, the Czech National Bank (and its Slovak counterpart) replaced the federal monobank, the State Bank of Czechoslovakia. The National Bank oversees all financial institutions. Numerous commercial and joint-venture banks developed after democratization. The banking industry suffered a major crisis in 1996, when the fifth and sixth largest banks failed. During the 1990s total foreign investment, particularly in the communications, transportation, and consumer goods industries, was greater than that of most other former Soviet bloc countries.

Trade. The Czech Republic depends on foreign trade to boost economic growth. Czechoslovakia was one of the largest foreign traders in eastern Europe and was a member of the Council for Mutual Economic Assistance (Comecon) until that organization disbanded in 1991. With democratization, trade patterns shifted, and by the end of the 1990s exports to former Comecon members had declined to about one-fourth of total exports. Germany is the country's main trading partner. Machinery and transportation equipment comprise the largest share of both exports and imports.

Transportation. Owing to terrain, settlement patterns, former federal policies, and geographic orientation toward western Europe, the Czech Republic possesses a more extensive transportation system than that of Slovakia. About 5,900 miles (9,500 kilometres) of rail lines serve all regions of the country and link the republic with its neighbours. Despite a modernization of the railways, there has been a steady decline in both passenger and freight operations; EuroCity trains connect Prague with most major European cities. An extensive network of more than 35,000 miles of paved roads crisscrosses the Bohemian Plateau, while a superhighway links Prague, Brno, and Bratislava.

The Elbe and the Vltava are the principal navigable rivers in the Czech Republic, with Děčín and Prague their chief ports, respectively. The Oder provides access to the Baltic Sea via the Polish port of Szczecin. Air service connects Prague with Ostrava, Brno, Karlovy Vary, and other regional centres, as well as with Bratislava in Slovakia.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. *Constitutional framework.* On Dec. 16, 1992, the Czech National Council adopted a new constitution establishing the Czech Republic as a parliamentary democracy. This document reflected the Western liberal tradition of political thought and incorporated many of the principles codified in the Charter of Fundamental Rights and Freedoms, which was adopted by the former Czechoslovak Federal Assembly in January 1991. The constitution provides for a bicameral Parliament consisting of a Chamber of Deputies (200 members elected on a proportional basis for four-year terms) and a Senate (81 members elected by district for six-year terms).

Executive power

Executive power is shared by the prime minister and the president, who is the representative head of state and is elected by a joint session of Parliament to a five-year term. The president, in turn, appoints a prime minister, who heads the government and advises the president on the appointment of other members of the government.

There is universal direct suffrage, and there are several prominent political parties, some of which represent particular interests, such as Gypsy (Roma) rights, environmentalism, and farmers' concerns.

Local government. The Czech Republic revised its administrative structure in 2000. The country is divided into 14 regions, which reflect the divisions that existed between 1948 and 1960, and 77 districts. Local governments have the power to levy local taxes and are responsible for roads, utilities, public health, and schools.

Justice. The judicial system consists of the 15-member Constitutional Court, the Supreme Administrative Court, and the Supreme Court, as well as high, regional, and district courts. Military courts are under the jurisdiction of the department of defense. During the 1990s, the Czech government took steps to modify its legal system to meet standards set by the Organization for Security and Cooperation in Europe.

Armed forces. The Soviet troop withdrawal from Czechoslovakia in mid-1991 coincided with the dissolution of the Warsaw Pact. At partition, apportioning military resources was one of the major tasks of the new Czech and Slovak defense ministries. Two-thirds of the matériel went to the Czech forces. The Czech military includes ground and air forces and frontier guards. In the 1990s Czech units served in the Balkans conflict as part of the international force of United Nations and NATO troops. In 1999 the Czech Republic (along with Poland and Hungary) joined NATO.

Education. Children 3 to 6 years old may attend state kindergartens. Compulsory education lasts 10 years, from age 6 to 16. Most students 15 to 18 years of age continue their education either at a general secondary school, which prepares them for college or university studies, or at a vocational or technical school. Since 1990 many private and religious schools have been established.

Enrollment in colleges and universities is low in comparison to many other European countries. The leading institutions of higher education, which provide four to five years of intensive study, have long-standing traditions. Charles University (founded 1348) and the Czech Technical University (founded 1707), both in Prague, are among the oldest universities of their kind in central Europe. Brno has two universities, and Olomouc has one. A number of teachers' colleges were redesignated as universities during the 1990s. Research work is carried out at universities and at special research institutions affiliated with the Academy of Sciences of the Czech Republic.

Universities

Health and welfare. To restructure the health care system inherited from the communist era, the Czech Republic sought to end state control of health services, create a health care system that would include privately administered facilities, and introduce a funding structure to underwrite the system. By 1994 privatization had been accomplished and the number of private health-care facilities had increased substantially. Simultaneously, there was a dramatic increase in costs, which proved difficult to address. Despite the increased cost of health care, however, Czechs generally benefited from greater access to advanced medical technologies and procedures.

Housing conditions are relatively good in comparison to other eastern and central European countries. However, there have been severe housing shortages, which were exacerbated during the 1990s, owing to the major political and economic changes. Czechs generally enjoy a higher standard of living than other former communist countries in Europe.

Increasing crime rates were a major problem in the 1990s. The lowering of entitlements for unemployment worked as a disincentive to registering for unemployment benefits and encouraged the spread of an illegal, "parallel" economy. There was also a large influx of political and economic refugees from Europe and elsewhere. Coupled with increasing mutual resentment between Czechs and the local Gypsy population, ethnically motivated violence was frequent in the late 1990s. (F.W.C./Mi.Ha./Ed.)

CULTURAL LIFE

Czech cultural traditions reflect a German and Slavic mixture. Influences from farther afield also have been strong. Visually the most striking influences are Italian—in Renaissance and Baroque architecture for instance—while literature, music, the visual arts, and popular culture are indebted to a variety of external influences. Most of the Western cultural influences on the Czech Lands have

passed through a German filter, and in response Czech cultural traditions are marked by a strong sense of national identity.

Literature. Czech literature can claim a remote ancestry in the vernacular writing connected with the mission sent to Moravia in AD 863 by the Byzantine emperor Michael III. Christianity had reached the Slavs of Moravia from the west under the influence of the Frankish empire. To counter this Frankish influence, Prince Rostislav, the ruler of Great Moravia, sought help from the east. The resulting mission was led by an experienced scholar and diplomat, Constantine (better known as Cyril), and his brother Methodius. The brothers translated much of the Bible and the essential liturgical texts into a Slavonic literary language of Cyril's devising, based on the Macedonian-Slavonic vernacular of his native Salonika but enriched from other sources, notably Greek and the Slavonic of Moravia.

Cyril and Methodius

The most noteworthy literary monuments of this language (now known as Old Church Slavonic) are the *Lives* of the two brothers, which were almost certainly written before 900 (though they are preserved only in later copies). Other Old Church Slavonic texts, however, can be assigned to the Czech era, notably the *Legends* about St. Wenceslas (Václav), prince of Bohemia (ruled 921–929), and his grandmother Ludmila, probably from the 10th century. The Old Church Slavonic language, employed for a while along with Latin, fell out of use after 1097, when the last Slavonic monastery in Bohemia was taken over by Benedictine monks. (Ro.Au./Z.A.B.Z.)

Writing in the Czech language emerged in the 13th century, establishing a generally continuous tradition. Chivalrous romances and chronicles, legends of the saints, love lyrics, satires, translations of the Bible, and religious prose were written in the 14th and 15th centuries. During the Counter-Reformation there was a serious decline in the social and administrative use of Czech, though the Baroque period brought fresh impulses to popular poetry and influenced both Roman Catholic and non-Catholic writers. A renewed flowering of Czech literature occurred during the 19th century (referred to as the Czech National Revival), a movement that later took on distinctly political overtones.

For the Czechs to become full-fledged members of the 19th-century community of European nations, their history had to be constructed and their language rediscovered, reconstructed, and codified. Josef Dobrovský, a Jesuit priest and scholar who wrote in German, published an outstanding systematic grammar of the Czech language. František Palacký, a historian turned politician, published the first volume of an ambitious history of the Czech nation in German in 1836. After 1848 Palacký continued his history in the Czech language only, though subsequent volumes appeared in both Czech and German.

Meanwhile, the Romantic literary movement of western Europe began to affect the emerging Czech literature. The Czech Romantic school of poetry, dating from the early 19th century, is best represented by Karel Hynek Mácha and Karel Jaromír Erben. In Bohemia the Romantic movement gave way in the 1840s to a more descriptive and pragmatic approach to literature. Božena Němcová's novel *Babička* (1855; "The Grandmother") became a lasting favourite with Czech readers, while the journalist and poet Karel Havlíček Borovský acquainted Czechs with some of the stark facts of political life. Jan Neruda, in his poetry and short stories, domesticated literary sophistication within a familiar Prague framework. Toward the end of the 19th century, the historical novels of Alois Jirásek began to claim a wide readership, while poetry moved through Parnassian, Symbolist, and Decadent phases.

The Czech Romantic school

The making, and breaking, of the Czechoslovak state between the two world wars was reflected in its literature. Jaroslav Hašek's sequence of novels *Osudy dobrého vojáka Švejka za světové války* (1921–23; *The Good Soldier Schweik*) made a mockery of authority, especially that of the former Austro-Hungarian army. Karel Čapek wrote popular plays, novels, and travel books, many of which have been translated into English. Vítězslav Nezval, František Halas, Vladimir Holan, Josef Hora, and Nobel Prize winner Jaroslav Seifert were among other writers whose poetry came to prominence during the first half of the 20th century. As World War II and German-imposed censorship closed in, poetry became even more popular than in peacetime: the brief life and work of Jiří Orten is an outstanding example of his tragic generation.

Before the destruction of Czech Jewry by the Nazis and the expulsion of the German minority at the end of the war, Bohemia and Moravia had a strong German literary tradition. About the mid-19th century, Adalbert Stifter's descriptions of nature and the common people inspired local followers in the borderland between Bavaria and Bohemia. During the first half of the 20th century, the German-Jewish group of writers in Prague—Franz Kafka, Franz Werfel, Rainer Maria Rilke, and Max Brod—achieved international recognition.

Among the postwar generation of writers, Bohumil Hrabal became well-known for his haunting short stories. While Hrabal remained largely apolitical, after 1948 the majority of Czech writers became enthusiastic members of the Communist Party. Communism had strong domestic roots and thrived as an ideology among intellectuals as well as organized workers, as communist propagandists successfully integrated strong doses of anti-German hatred with pan-Slavic solidarity and socialist visions of utopia. However, the Stalinist purges of the 1950s and the uprisings of 1956 discredited the party and gave birth to a reform movement. Before and after the invasion of Czechoslovakia by Warsaw Pact forces in 1968, Czech writers were at the forefront of the communist reform movement. Many suffered for their political commitment; a number of writers, including Milan Kundera and Josef Škvorecký, were forced to live and work abroad. Ludvík Vaculík and Ivan Klíma, writers of the same generation and of similar conviction, were among those whose novels were circulated in Prague as underground publications. Since 1989 Czech writers have continued to have a major political influence, perhaps best exemplified by the election of Václav Havel, a prominent dissident playwright, as the country's first postcommunist president.

Theatre. The Czech Republic's theatrical tradition is usually connected with the Prague National Theatre, which was completed in 1881. In the 1930s the "liberated theatre" movement made popular by two comic actors, Jiří Voskovec and Jan Werich, and the musician Jaroslav Ježek launched a new genre of political satire. Czech stage designers such as František Tröster, František Muzika, Josef Čapek, and Josef Svoboda achieved worldwide recognition. Václav Havel's best-known and most-translated plays are *Zahradní slavnost* (1963; *The Garden Party*) and *Vyrozumění* (1965; *The Memorandum*).

"Liberated theatre" movement

Music. During the 18th century, Bohemia produced several musicians and composers who greatly influenced musical styles throughout Europe. Johann Stamitz, the founder of the Mannheim school of symphonists, made key contributions to the development of the classical symphonic form and had a profound influence on Mozart. During the 19th century, operatic and symphonic music retained an important place in Czech cultural life. Bedřich Smetana injected Czech nationalism into his works. Antonín Dvořák, Leoš Janáček, and Bohuslav Martinů drew heavily on folk music and achieved international fame. Since World War II, Czech musicians have gained notice on the European jazz circuit, and jazz-rock keyboardist Jan Hamr (Jan Hammer) won international acclaim for his television and motion picture soundtracks.

Film. During the communist era, film was valued as a propaganda tool, and the state-supported Czechoslovak motion picture industry produced an average of 30 feature films annually. With the withdrawal of state sponsorship during the 1990s, fewer than 20 films appeared each year. Despite the limitations imposed by a small market, Czech films and film directors have made their international mark. Among the best known internationally are those of the Czech New Wave period (1962–68), including Miloš Forman's *Lásky jedné plavolvlásky* (1965; *Loves of a Blonde*) and Jiří Menzel's *Closely Watched Trains* (1967), which won an Academy Award. In 1997 Jan Svěrák's film *Kolya,* set just before the Velvet Revolution, also received international acclaim.

Fine, applied, and folk arts. The Czechs have a strong tradition in the graphic arts. This includes many forms of caricature: Josef Čapek, the brother of the writer Karel Čapek, is remembered for a series of drawings, entitled *The Dictator's Boots,* which date from Adolf Hitler's rise to power. Much of Czech graphic art derived its inspiration from popular, narrative art, such as the happy marriage between Hašek's texts and Josef Lada's illustrations. Since the 19th century, Czech painters and graphic artists have generally followed the broad European movements, but realism usually prevailed. One of the best-known painters of the 19th century was Josef Mánes. Paris-based Art Nouveau illustrator Alphonse (Czech: Alfons) Mucha captured the fin-de-siècle mood in his paintings and posters, which gained him world renown. During the 20th century, Czech painters such as František Kubka, Emil Filla, Toyen, Jindrich Štyrský, and Josef Šíma were influenced by Cubism and Surrealism. Prominent painters active since the mid-20th century include Jan Zrzavý, Mikuláš Medek, Adriena Šimotová, Jan Bauch, and Jiří Kolář.

In the applied arts, manufactured glass ornaments, traditional northern Bohemian costume jewelry, and toys are internationally known. Popular art has been preserved most often in useful ceramic and wood objects; embroideries and traditional costumes are now less important.

Libraries and museums. The Czech Republic's network of public libraries dates to the 19th century. The largest library is the National Library in Prague, created in 1958 by the merger of several older libraries. Other major collections are in the National Museum Library, also in Prague and founded in 1818, and the State Scientific Library in Brno. Of the republic's many museums, three in Prague are especially noteworthy: the National Museum (founded 1818), the National Gallery (1796), and the Museum of Decorative Arts (1885), the last housing one of the world's largest collections of glass.

Sports and recreation. Czechs enjoy a variety of outdoor activities including football (soccer), golf, canoeing, and cycling, as well as winter sports such as cross-country skiing, snowboarding, and ice hockey. The country's national ice hockey team won four world championships from 1996 to 2001 (including three consecutive) and the gold medal at the 1998 Olympic Games. Several of the country's most prominent players, such as Dominik Hašek and Jaromír Jágr, performed in North America's National Hockey League. International tennis stars Ivan Lendl and Martina Navratilova were both native Czechs.

Press and broadcasting. Until 1989 the media were subject to censorship through the government's Office for Press and Information. The government owned all telephone, telegraph, television, and radio systems, and news was disseminated by the official Czechoslovak News Agency. State control of radio and television ended in 1991, and during the 1990s many new newspaper and book publishers were established. (Z.A.B.Z./Mi.Ha./Ed.)

For statistical data on the land and people of the Czech Republic, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Establishment of the republic

The Czech Republic came into existence upon the dissolution of the Czechoslovak federation on Jan. 1, 1993. Upon partition, the Czech Republic was given two-thirds of the federation's assets; special agreements were made for the diplomatic service and the armed forces. The citizens of the former federation also were divided on the basis of new nationality laws, and, soon after partition, many Slovaks applied for Czech citizenship.

Václav Havel, the first postcommunist president of Czechoslovakia, was elected the republic's president in 1993. The government immediately faced the problem of monetary arrangements with Slovakia and decided that a monetary union would be unworkable. Although the separation with Slovakia was amicable, customs posts were erected along the Czech-Slovak border, and there were signs of rising national tempers.

During much of the 1990s, the Czech Republic dealt with a variety of internal issues, including the restitution of property expropriated from Jews during Nazi occupation, the rights of former communists to hold senior government posts, and relations with its minority Roma (Gypsy) population. In foreign affairs, the Czech Republic focused much of its efforts on forging a new relationship with Slovakia and in reorienting itself toward western Europe; in 1999 the Czech Republic joined the North Atlantic Treaty Organization, and in 2004 it became a member of the European Union. (Z.A.B.Z./Ed.)

For later developments in the history of the Czech Republic, see the BRITANNICA BOOK OF THE YEAR.

Slovakia

The mountainous, landlocked Slovak Republic (Slovak: Slovenská Republika) is roughly coextensive with the historical region of Slovakia, the easternmost of the two territories that from 1918 to 1992 constituted Czechoslovakia. Slovakia became independent on Jan. 1, 1993. The country is bordered by its former federal partner—the Czech Republic—to the west, Poland to the north, Ukraine to the east, Hungary to the south, and Austria to the southwest. It has an area of 18,933 square miles (49,035 square kilometres). The capital is Bratislava.

THE LAND

Relief. The Western Carpathian Mountains dominate the topography, consisting of three regions of east-west-trending ranges—Outer, Central, and Inner—separated by valleys and intermontane basins. Two large lowland areas north of the Hungarian border, the Little Alfold (called the Podunajská, or Danubian, Lowland in Slovakia) in the southwest and the Eastern Slovakian Lowland in the east, comprise part of the Inner Carpathian Depressions region.

The Outer Western Carpathians to the north extend into the eastern Czech Republic and southern Poland and contain the Little Carpathian (Slovak: Bielé Karpaty), Javorníky, and Beskid (Beskydy) mountains. The Central Western Carpathians across central Slovakia include the country's highest ranges: the High Tatra (Vysoké Tatry) Mountains, containing the highest point in the republic, Gerlachovský Peak, at 8,711 feet (2,655 metres); and, to the south, the Low Tatra (Nízke Tatry) Mountains, which reach elevations of about 6,500 feet. Farther to the south are the Inner Western Tatra Mountains, which extend into Hungary and contain the economically important Slovak Ore (Slovenské Rudohorie) Mountains.

Tatra Mountains

Drainage and soils. Slovakia drains predominantly southward into the Danube (Dunaj) River system. Two major rivers, the Morava and the Danube, form the republic's southwestern border. The principal rivers draining the mountains include the Váh, Hron, Hornád, and Bodrog, all flowing south, and the Poprad, draining northward. Flows vary seasonally. Mountain lakes and mineral and thermal springs are numerous.

Slovakia contains a striking variety of soil types. The country's richest soils, the black chernozems, occur in the southwest, although the alluvial deposit known as Žitný (Rye) Island occupies the core of the Slovakian Danube basin. The upper reaches of the southern river valleys are covered with brown forest soils, while podzols dominate the central and northern areas of middle elevation. Stony mountain soils cover the highest regions.

Climate. Slovakia has a more continental climate than the Czech Republic. The mean annual temperature drops to 25° F (−4° C) in the High Tatras, rising to 51° F (11° C) in the Danube lowlands. Average July temperatures exceed 68° F (20° C) in the Danube lowlands, and average January temperatures can be as low as 23° F (−5° C) in mountain basins. The growing season is about 200 days in the south and less than half that in the mountains. Annual precipitation ranges from 22 inches (570 millimetres) in the Danube plains to more than 43 inches in windward mountain valleys. Maximum precipitation falls in July, while the minimum is in January.

Precipitation

Plant and animal life. Although Slovakia is small, its varied topography supports a wide variety of vegetation. Agriculture and timber cutting have diminished the republic's original forest cover, but approximately half of its area is still forested. The major forest types include the

Štrbské Pleso, a morainic lake in the High Tatras, High Tatra National Park, Slovakia.
František Malecek

oak-grove assemblages of the Podunajská Lowland, the beech forests of the lower elevations of the Carpathians, and the spruce forests of the middle and upper slopes. The highest elevations support taiga and tundra. The country's forestland is most extensive in the mountainous districts. The timberline runs at about 5,000 feet. At these upper elevations, particularly in the Tatras, the tree cover below the timberline consists largely of dwarf pine. At around 7,500 feet, Alpine grasses and low-growing shrubs give way to lichens.

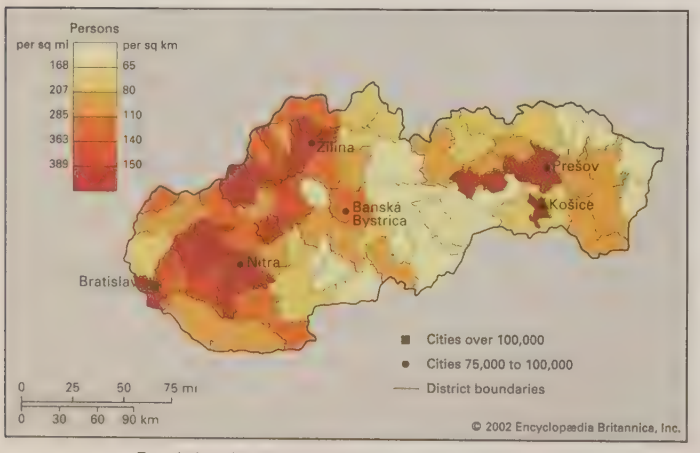
Slovakia's wildlife is abundant and diverse; the High Tatra National Park shelters an exceptional collection of wild animals, including bears, wolves, lynx, wildcats (*Felis sylvestris*), marmots, otters, martens, and minks. Hunting is prohibited in the parks. Some animals, such as the chamois, are protected nationwide. The forests and lowland areas support numerous game birds, such as partridge, pheasant, wild geese, and ducks. Raptors, storks, and other large birds are protected.

National parks

The country has seven national parks. The High Tatra and Pieniny parks are situated along the Polish border and are administered in cooperation with Polish authorities; the Low Tatra National Park is located in the interior. All three of these areas preserve many species of wildlife, along with glacial landscapes, Alpine flora and fauna, and relict species from the Pleistocene glaciations (*i.e.*, those that occurred from about 1,600,000 to 10,000 years ago).

Settlement patterns. Slovakia's population density is relatively low, largely because of its rugged terrain. Highland villages, many of them dating from the Middle Ages, conform to linear ridges and valleys. Dispersed settlement occurs along the Czech border and in the central mountains, reflecting the later colonization of the 17th and 18th centuries. Rural settlements with up to several hundred inhabitants tend to prevail except in the more heavily urbanized southwest. The most concentrated population is found on the Podunajská Lowland. Collectivization of farmland under Czechoslovakia's communist regime supplanted the ancient small-scale pattern of land use with a giant agricultural grid. Reprivatization of farmland following the events of 1989 effected a gradual reconfiguration of the arable landscape.

Postwar industrialization programs increased urbanization. Three-fifths of the population lives in urban areas. In addition to Bratislava, regional centres include Nitra, Banská Bystrica, Žilina, Košice, and Prešov.



Population density of Slovakia.

THE PEOPLE

Ethnic composition. Slovakia's population is about 85 percent Slovak. Hungarians, concentrated in the southern border districts, form the largest minority, comprising about one-tenth of the population. Small numbers of Czechs, Germans, and Poles live throughout the country, while Ruthenians (ethnic Ukrainians) are concentrated in the east and northeast. There is a sizable and relatively mobile population of Gypsies (Roma), estimated at roughly 2 percent of the population, who live mainly in the eastern part of the country.

Languages. The majority of the population identify Slovak as their first language, but there is widespread fluency in Czech. As members of the West Slavic language group, these closely related and mutually intelligible languages use the Roman rather than the Cyrillic alphabet. Slovak as a literary language dates to the 19th century. Hungarian, Polish, German, Ukrainian, Russian, and Romany are among the other languages spoken in Slovakia. In 1996 a controversial law established Slovak as the nation's official language.

Religions. Four decades of official atheism ended in 1989, and the widespread persistence of religious affiliation became quickly visible in both the sectarian and political spheres. Three-fifths of the population are Roman Catholic, but the Protestant Lutheran and Calvinist churches claim a significant minority of adherents. Eastern Orthodoxy remains strong in Ruthenian districts.

Demographic trends. Historically, emigration to other countries kept Slovakia's growth rate low. Well over half a million Slovaks emigrated to the United States prior to

1914. During communist rule, emigration virtually ceased. Industrialization policies were responsible for significant internal migration and increased urbanization. Slovakia's birth rate outpaces its death rate, and the number of elderly citizens has steadily increased.

THE ECONOMY

The brevity of the fanfare that greeted the rebirth of Slovakia in 1993 was largely an acknowledgement of economic reality. Slovak political autonomy was popular, but many viewed the pursuit of it outside the Czechoslovak federation as potentially disastrous. Others argued that the conversion to a market economy in a federated Czechoslovakia would favour the Czech region. Geographic and historical conditions, including the central planning of the communist era, had left Slovakia more rural and less economically diversified than its Czech neighbour. Indeed, the process of privatization undertaken after the fall of the communist regime in 1989 proceeded much more slowly in Slovakia than in the Czech Republic. Furthermore, since Czechs had long dominated the federal leadership of Czechoslovakia, the Slovak regional leaders lacked experience at the national level, compounding the burden of Slovak independence.

Initially, the engineers of Czechoslovakia's political separation had assumed that the two countries could share, for a limited period, the existing monetary system. This arrangement was quickly considered untenable: Czechs foresaw contagious inflation in Slovakia, and Slovaks feared economic "shock therapy" by the Czechs. The short-lived plan that emerged prescribed a stepped transition in which each republic would recall a portion of its Czechoslovak currency supply for stamping with a country mark, and newly printed bills would gradually replace the stamped ones. The agreement established an initial exchange rate of 1 to 1 for the new currencies. However, the two nations soon adopted separate currencies.

The apportionment of government assets presented a major challenge, particularly those of the former Czechoslovak military. Although Slovakia accounted for as much as two-thirds of the federation's arms production, the majority of bases, aircraft, and associated equipment were on Czech soil. Slovakia's economy suffered an economic downturn in the early 1990s, prompting the government to implement a privatization program. By the end of the century, approximately three-fourths of Slovakia's gross domestic product was generated by the private sector.

Resources and power. Slovakia has limited but economically important reserves of brown coal and lignite near Handlová and Modrý Kameň. Pipelines import Russian oil and natural gas, the latter supplementing existing supplies. A natural-gas field was discovered near the western town of Gbely in 1985.

Mineral deposits

Substantial deposits of iron ore, copper, manganese, magnesite, lead, and zinc are mined in the Slovak Ore Mountains. Imported bauxite and nickel ore are refined at Žiar nad Hronom and Sered', respectively. Eastern Slovakia has some economically significant salt deposits.

The chief energy source for industry is hydroelectric power, generated by a series of dams on the Váh, Orava, Hornád, and Slaná rivers. In 1977 the Czechoslovak and Hungarian governments agreed to build a major hydroelectric project on the Danube southeast of Bratislava at Gabčíkovo. The project called for the diversion of the Danube and the construction of two dams to be built by each country. In 1989 Hungary withdrew from the venture. In 1997 the International Court of Justice ruled that both states had violated the agreement and advised Slovakia and Hungary to negotiate a new agreement that would specify more stringent environmental standards, though neither nation was inclined to do so.

Nuclear power plants generate a substantial portion of Slovakia's electricity. To meet European safety regulations, the Slovak government agreed to decommission two potentially hazardous Soviet-era reactors by 2008.

Agriculture and forestry. During communist rule, agriculture was subordinate to industrialization. By the end of the 20th century, only about one-third of Slovakia's territory was cultivated. On the fertile lowlands, wheat, barley, sugar beets, corn (maize), and fodder crops are important, but on the relatively poor soils of the mountains the principal crops are rye, oats, potatoes, and flax. Tobacco and fruits are grown in the Váh valley, and vineyards thrive on the slopes of the Carpathian ranges in the southeastern part of the country. On the plains, farmers raise pigs and cattle, while sheep raising is prevalent in mountain valleys. Despite reforestation efforts, nearly one-third of Slovakia's forests were destroyed or seriously damaged by 1989.

Industry. Because it was the location of some of eastern Europe's most inefficient state-run industries, Slovakia, in some ways, has felt the effects of economic reform more acutely than has its former federal partner. Bratislava, Košice, and the towns along the Váh River are Slovakia's main manufacturing centres. Important industries include ceramics, chemicals, machinery, steel, textiles, food and beverage processing, and petroleum products. Slovakia's armaments industry has revived since 1993 and produces military equipment primarily for export. Environmental pollution—the legacy of communist-era industrialization—is a pressing concern.

Tourism. During the communist period, most visitors were from eastern Europe. As in the Czech Republic, since independence, tourism has dramatically increased from western Europe and North America. Attractions include mountain scenery, caves, castles and other historical buildings and monuments, arts festivals, and numerous thermal and mineral springs.

Finance and trade. The National Bank of Slovakia succeeded the Czech and Slovak central bank as the republic's principal financial institution. It governs monetary policy, ensures the stability of the Slovak currency, the koruna, and oversees the republic's commercial banks. Following decentralization of the banking system, a number of commercial and joint-venture banks developed. However, during the mid-1990s several banks were shuttered as the result of financial scandals. A stock exchange operates in Bratislava.

Direct foreign investment

Slovakia's well-educated labour force helps attract foreign investors from Austria and Germany as well as other Western nations. In general, though, direct foreign investment lags behind that of other former Eastern-bloc countries. During the late 1990s, the government established tax incentives to stimulate foreign investment.

Slovakia depends on foreign trade to boost economic growth. Following the dissolution of the Council for Mutual Economic Assistance (Comecon), trade with former eastern European countries declined, while that with Western countries expanded. The volume and profile of trade between Slovakia and the Czech Republic remains important despite occasional disruptions stemming from political squabbles. Slovakia's principal trade partners include the Czech Republic, Russia, Germany, Italy, Poland, and Austria.

Transportation. Slovakia's transport system is relatively modern, though somewhat inefficient. Its most important element is the railways, which provide the bulk of freight transport. With assistance from the European Investment Bank, Slovakia has sought to electrify its entire rail system. Development of the highway network, which is not very extensive, proceeded at a slower pace than that of the railway system. A superhighway from Bratislava to Brno and Prague was begun in 1938 but completed only in 1980.

The Danube River, forming the western third of the border with Hungary, dominates water transport. Komárno and Bratislava are the country's principal ports. Interior rivers are not navigable. There are airports at Bratislava, Lučenec, Žilina, Zvolen, Poprad, and Košice; however, most international travelers to Bratislava use Vienna's airport, which is 40 miles (60 kilometres) west of the Slovak capital.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. *Constitutional framework.* The Slovak National Council adopted a new constitution on Sept. 1, 1992, four months before the federation's partition. This document—like its Czech counterpart—reflects the Charter of Fundamental Rights and Freedoms passed by the former Czechoslovak Federal Assembly in 1991. The con-

National Council

stitution provides for a unicameral legislature (the National Council), consisting of 150 deputies chosen by direct general election. The head of state, the president, is elected for a five-year term. The 1992 constitution specified that the president was to be elected by a three-fifths majority of the National Council. However, after several years of considerable controversy, in 1999 the government approved a constitutional amendment that allowed for the direct election of the president. The supreme executive body is the government, which is formed by a prime minister, whom the president appoints.

Local government. The constitution addresses the issue of local administration only cursorily, defining the municipality as a territorial and administrative entity exercising jurisdiction over its permanent residents. Slovakia is composed of eight administrative regions (including Greater Bratislava) and 79 districts.

Justice. The apex of the Slovak judicial system is the Constitutional Court, comprising 10 judges appointed by the president for seven-year terms. The lower courts resolve civil and criminal matters and assess the legality of administrative rulings. Slovakia's civil law code is based on Austro-Hungarian codes but has been revised to eliminate language dating from the communist era and to comply with requirements set by the Organization on Security and Cooperation in Europe (OSCE).

Armed forces. With the Soviet troop withdrawal and the dissolution of the Warsaw Pact in 1991, Czechoslovakia assumed control of its own military affairs. The apportionment of formerly federal military property between the two new republics was a major hurdle in the partition process, as was the creation of separate armed forces.

Slovakia's armed forces comprise an army and an air force of approximately 50,000 troops. There also are separate civil defense troops and internal security forces. Military service is compulsory for all men over age 18. During the 1990s Slovakia participated in peacekeeping efforts in Albania, Angola, Croatia, and Syria. In 1994 Slovakia joined NATO's Partnership for Peace program.

Education. The Slovak constitution guarantees free primary and secondary public education. There are also a number of private and church-affiliated schools. Kindergartens are available for children 3 to 6 years old. Education is compulsory between the ages of 6 and 16 and usually includes instruction in a major foreign language. General secondary schools offer preparation for university study. Vocational secondary schools provide training in technical and clerical fields and the service industries.

Universities

Slovakia has nearly 20 higher education institutions, of which the largest and oldest is Bratislava's Comenius University (founded 1919). Also in Bratislava are the Slovak Technical University, the University of Economics, the Slovak Academy of Sciences, and several arts academies.

Health and welfare. The 1992 constitution retained guarantees of free health care under a public insurance program. The health care system remains largely under state control, though private facilities and private medical insurance have been introduced. Factory and community clinics, first-aid stations, and other outpatient facilities supplement the national system of hospitals. In addition, spas such as Bardejov (established in the 13th century) have long been a feature of Slovak health care.

Housing shortages have been severe, and many of the urban high-rise housing estates dating from the 1970s are in ill-repair. In the cities and towns, almost all housing units are supplied with electricity, water, and bathrooms. Housing in some rural areas is inferior.

Slovakia's standard of living is generally adequate, though members of the Gypsy minority frequently have a much lower standard of living than the general population, owing to high unemployment and discrimination. Higher wages prevail in the urban and industrial areas. Unemployment is a significant problem outside the major cities. As in the Czech Republic, there was an increase in crime in the 1990s. (F.W.C./Mi.Ha./Ed.)

CULTURAL LIFE

The antecedents of a distinct Slovak culture date from the mission sent to Moravia in AD 863 by the Byzantine emperor Michael III at the request of the Moravian prince Rostislav; the Moravian state then encompassed at least part of the territory of present-day Slovakia. Byzantine influence was short-lived, however, disappearing from the region after the invasions by nomadic Magyar tribes toward the end of the 9th century. Thus the South Slavs were separated from the Western Slavs living north of the Danube River, and, as the territory of Slovakia came under Magyar control, it became known as Upper Hungary.

Literature. Slovak dialects are related to Czech, but they have been distinct since the Middle Ages. No systematic attempt was made, however, to develop a Slovak literary language, although in the 18th century devotional texts were produced with an increasingly local flavour. Josef Ignác Bajza wrote the didactic novel *René* (1783–85) in heavily Slovak-influenced Czech. Finally, Anton Bernolák consolidated a Slovak literary form in a grammar (1790) and a six-volume dictionary (1825–27), using the western Slovak dialect as a base. The poet Ján Kollár, using this language, completed *Slávy dcera* ("The Daughter of Sláva") in 1824, which, in the Romantic literary tradition, celebrated the common past of the Slavs. Ján Hollý, who wrote lyrics, idylls, and national epics, also used Bernolák's language.

The Slovak Protestant minority continued to use Czech as their liturgical language. Another attempt to codify literary Slovak was made by L'udovít Štúr, this time based on the commonly spoken dialect of central Slovakia. Štúr's new idiom was quickly taken up by a group of poets, including Andrej Sládkovič (Andrej Braxatoris), whose *Marína* (1846) became a national epic. The most significant figure was Janko Král', whose exploits in the Revolutions of 1848 made him a legend. His writings are among the most original works of Slavonic Romanticism.

Lyric poetry

In the 20th century, the strength of Slovak literature was in lyric poetry. The preeminent poet before World War I was Hviezdoslav (Pavol Országh), who enriched Slovak poetic language with original work and translations. Other notable poets were Svetozár Hurban Vajanský and Ivan Krasko (the pseudonym of Ján Botto), whose volumes of verse *Nox et solitudo* (1909) and *Verše* (1912) were among the most notable achievements of Slovak literature.

After the war, the leading lyric poets were Martin Rázus, Janko Jesenský, Emil Boleslav Lukáč, Ján Smrek (Ján Aietek), Ján Poničan, and Laco Novomeský. In fiction, the country tales by Timrava (Božena Slančíkova), a vast chronicle of 20th-century Slovakia by Milo Urban, and the lyrical prose of Margita Figuli were outstanding. The difficulties of World War II and its aftermath of communist rule found vivid, personal expression in the work of Ladislav Mňačko, Alfonz Bednár, and Dominik Tatarka. While Mňačko was among the first eastern European writers to criticize Stalinism, in the novel *Ako chutí moc* (1967; *The Taste of Power*), Tatarka attacked the Husák regime's process of "normalization" in Czechoslovakia after 1969 in *Sám proti noci* (1984; "Alone Against the Night"). In the years leading up to the Velvet Revolution, novelists such as Ladislav Ballek, Vincent Šikula, and Ján Johanides asserted a distinct Slovak voice. Martin Šimečka's novel *Džin* (1990; *The Year of the Frog*), set in the Czechoslovakia of the mid-1980s, recounts the life of a young man who is barred from a university education because of his father's anticommunist activities. During the 1990s a new generation of writers, including Dušan Mitana and Pavel Vilikovský, distinguished themselves. Milan Rufús is generally considered Slovakia's preeminent contemporary poet.

Music and theatre. Music occupies an important place in Slovak cultural life. Its development has been traced to Roman times, and it was nurtured by the Roman Catholic church and by the Magyar nobility. In addition, a strong folk tradition developed, which became an object of scholarly interest in the first half of the 19th century, when a separate national musical tradition began to emerge under the influence of such composers as Frico Kafenda. Modern Slovak music has drawn from both classical and folk traditions, particularly with the generation of composers that gained prominence after World War I, including Andrej Očenáš and Mikuláš Moyzes. Slovakia's leading orchestra is the Slovak Philharmonic. Opera singer Lucia Popp performed internationally during the 1970s and '80s.

Modern Slovak music

Slovak drama developed at about the same time as Slovak literature; Juraj Palkovič's play *Dva buchy a tri šuchy* (1800; "Two Bangs and Three Ripples") is considered the first example. Ján Chalupka produced a lively satire, *Kocúrkovo,* in 1830, while Ján Palárik wrote his popular comedies in the 1850s and '60s, including *Inkognito* (1857) and *Zmeranie* (1862; "Measurement"). The first professional theatre featuring performances in the Slovak language was the Slovak National Theatre in Bratislava, established in 1920. Now the state subsidizes a number of theatre companies including several professional minority theatres.

Fine and applied arts. Slovak painters typically have looked outside the country for inspiration, particularly to Prague. At the end of the 19th century, however, Slovakia was "discovered" by Mikoláš Aleš from Bohemia and Jožа Úprka from Moravia. After 1918 a number of Slovak painters studying in Prague developed the "descriptive realism" school.

The Slovak film industry emerged in the 1920s. Notable from this period is the silent film *Jánošík* (1921), based on the life and legend of the Slovak folk hero. Of the films produced after World War II, perhaps the best known internationally are *The Shop on Main Street* (1965), directed by Ján Kadár and Elmar Klos, which received an Academy Award, the first ever awarded to a Czechoslovak, and *Ostře sledované vlaky* (1966; *Closely Watched Trains*), directed by Jiří Menzel. Like Kadár and Menzel, Juraj Jakubisko, whose strongly visual, metaphorical films include *Nejasná zpráva o konci sveta* (1997; *An Ambiguous Report About the End of the World*), was among the film directors who first gained acclaim during the late 1960s as part of the Czech New Wave.

Czech New Wave

Libraries and museums. The Slovak National Library is in Martin, while the Slovak Technical Library and the University Library are in Bratislava. Most major museums, including the Slovak National Museum (founded 1893) and the Slovak National Gallery (founded 1948), are located in Bratislava. The Museum of Jewish Culture, a part of the Slovak National Museum, opened in 1991.

Sports and recreation. Given the country's mountainous terrain, hiking, mountaineering, downhill skiing, and rock climbing are popular sports. Other outdoor sports such as fishing, white-water rafting, ice skating, cycling, spelunking, and horseback riding attract large numbers of enthusiasts. Among spectator sports, football (soccer) and ice hockey draw the largest crowds. Slovak athletes participated in the Olympic Games as members of the Czechoslovak team until 1994, when the republic competed as a separate country at the Winter Games at Lillehammer, Nor. Slovakia won its first Olympic medals in canoe events at the 1996 Summer Games in Atlanta, Ga.

Press and broadcasting. Slovakia has a number of Slovak-language daily newspapers. *Nový čas* ("New Time") and *Pravda* ("Truth"), formerly the organ of the Communist Party but now independent, have the largest circulations. The state subsidizes a number of periodicals in Hungarian, Czech, Ukrainian, German, and Romany.

The state-controlled monopolies on newspaper and book publishing were broken up with greater ease in Czechoslovakia after 1989 than was the monopoly in broadcasting. The division of Czechoslovakia, however, brought about the collapse of the federal broadcasting system in 1993. Both state-sponsored and commercial radio and television stations operate in Slovakia. (Z.A.B.Z./Mi.Ha./Ed.)

For statistical data on the land and people of Slovakia, see the *Britannica World Data* section of the BRITANNICA BOOK OF THE YEAR.

HISTORY

The Slovak Republic was established following the dissolution of the Czechoslovak federation on Jan. 1, 1993. The new prime minister, Vladimír Mečiar, and his Czech counterpart, Václav Klaus, had been the strongest proponents of separation. Although a renewed sense of national pride welled up in Slovakia, so, too, did a feeling of apprehension about the republic's future. This uneasiness manifested itself in the large numbers of Slovaks that applied for Czech citizenship immediately after partition.

Slovakia generally was considered a junior partner in the federation, but that arrangement provided the republic with a degree of political security and economic stability that became less certain with independence. Long-standing political differences and tensions with neighbouring countries, most notably with Hungary regarding its concerns about the future of the large Hungarian minority in southern Slovakia, that had been suppressed during the period of Soviet hegemony reemerged. In addition, economic forecasts for Slovakia generally were less optimistic than those for the Czech Republic. Slovakia inherited an economy dependent on large-scale but obsolete heavy industry, and the country faced rising unemployment and poor prospects for foreign investment.

Relations with Hungarian minority

During the early and mid-1990s the government focused much of its attention on reviving the economy and attempting to ease relations with its minority Hungarian population. It reoriented its foreign policy toward western Europe, seeking membership in the North Atlantic Treaty Organization and the European Union (EU). Mečiar's sometimes autocratic government was criticized by the international human rights community for use of intimidation tactics against opponents, including its support for an antisubversion law (which was eventually rejected) that critics charged would have allowed the government to restrict individual freedoms. The government also sparked widespread protests for twice canceling referendums on political reform.

In 1998 the opposition scored dramatic successes, with a four-party coalition replacing Mečiar with Mikulas Dzurinda. Dzurinda's government focused on meeting economic and political criteria for entry into the EU. In 1999, for example, Dzurinda allayed the concerns of several EU countries regarding Slovakia's treatment of minorities, securing passage of legislation that provided equal status for any language in an area where it was spoken by at least 20 percent of residents. He also engineered the country's entry into the Organization for Economic Co-operation and Development in 2000. Confirming the country's integration with the West, Slovakia was admitted to both the EU and NATO in 2004. (Z.A.B.Z./Ed.)

For later developments in the history of Slovakia, see the BRITANNICA BOOK OF THE YEAR.

BIBLIOGRAPHY

History. *General works:* CAROL SKALNIK LEFF, *The Czech and Slovak Republics: Nation Versus State* (1997, reissued 1998), examines national and state identity issues after partition. JAROSLAV KREJČÍ and PAVEL MACHONIN, *Czechoslovakia, 1918–92. A Laboratory for Social Change* (1996), provides a socioeconomic analysis of the early postcommunist years. JIŘÍ MUSIL (ed.), *The End of Czechoslovakia* (1995), is a collection of English-language essays on the breakup of Czechoslovakia. OSKAR KREJČÍ, *Czechoslovak National Interests* (1996), is an analysis of the end of communism from a communist perspective. ERIC STEIN and LLOYD CUTLER, *Czecho/Slovakia: Ethnic Conflict, Constitutional Fissure, Negotiated Breakup* (1997), offers a social history perspective on the breakup of Czechoslovakia. Other historical studies include WILLIAM V. WALLACE, *Czechoslovakia* (1976); NORMAN STONE and EDUARD STROUHAL (eds.), *Czechoslovakia: Crossroads and Crises, 1918–88* (1989); and JAROSLAV KREJČÍ, *Czechoslovakia at the Crossroads of European History* (1990).

The historical regions to 1914: FRANCIS DVORNIK, *Byzantine Missions Among the Slavs: SS. Constantine-Cyril and Methodius* (1970), illuminates the early medieval period of the region. The history of the region under Habsburg rule is found in ROBERT JOSEPH KERNER, *Bohemia in the Eighteenth Century: A Study in Political, Economic, and Social History, with Special Reference to the Reign of Leopold II, 1790–1792* (1932, reprinted 1969); and R.J.W. EVANS, *The Making of the Habsburg Monarchy, 1550–1700: An Interpretation* (1979, reissued 1991).

Czechoslovakia: The formation of the Czechoslovak federation is addressed in KAREL KAPLAN, *The Short March: The Communist Takeover in Czechoslovakia, 1945–1948* (1987; originally published in German, 1981); ROMAN SZPORLUK, *The Political Thought of Thomas G. Masaryk* (1981); Z.A.B. ZEMAN, *The Masaryks: The Making of Czechoslovakia* (1976, reissued 1990), and *The Break-Up of the Habsburg Empire, 1914–1918: A Study in National and Social Revolution* (1961, reprinted 1977); and VICTOR S. MAMATEY and RADOMÍR LUZA (eds.), *A History of the Czechoslovak Republic, 1918–1948* (1973). Czechoslovakia's fate during World War II is presented in THEODORE PROCHÁZKA, SR.,

The Second Republic: The Disintegration of Post-Munich Czechoslovakia, October 1938–March 1939 (1981); VOJTECH MASTNY, *The Czechs Under Nazi Rule: The Failure of National Resistance, 1939–1942* (1971); PETER G. STERCHO, *Diplomacy of Double Morality: Europe's Crossroads in Carpatho-Ukraine, 1919–1939* (1971); and F. NEMEC and V. MOUDRY, *The Soviet Seizure of Subcarpathian Ruthenia* (1955, reprinted 1981). The period leading up to and including the Soviet invasion of 1968 is covered in HANS RENNER, *A History of Czechoslovakia Since 1945* (1989), which focuses in particular on the events of 1968; Z.A.B. ZEMAN, *Prague Spring* (1969); H. GORDON SKILLING, *Czechoslovakia's Interrupted Revolution* (1976); ZDENEK MLYNÁR, *Nightfrost in Prague: The End of Humane Socialism* (1980; originally published in Czech, 1978); and I. WILLIAM ZARTMAN, *Czechoslovakia: Intervention and Impact* (1970). WILLIAM SHAWCROSS, *Dubcek*, rev. and updated ed. (1990), is also useful. The dissident role played by writers and journalists is examined in FRANK L. KAPLAN, *Winter into Spring: The Czechoslovak Press and the Reform Movement, 1963–1968* (1977); and A. FRENCH, *Czech Writers and Politics, 1945–1969* (1982). BERNARD WHEATON and ZDENEK KAVAN, *The Velvet Revolution: Czechoslovakia, 1988–1991* (1992), describes the popular revolution of 1989 and subsequent events.

History of the Czech lands: The kingdom of Bohemia in the 14th and 15th centuries, especially the Hussite movement and its aftermath, is discussed in RUBEN ERNEST WELTSCH, *Archbishop John of Jenstein (1348–1400): Papalism, Humanism, and Reform in Pre-Hussite Prague* (1968); HOWARD KAMINSKY, *A History of the Hussite Revolution* (1967); FREDERICK G. HEYMANN, *John Žižka and the Hussite Revolution* (1955, reissued 1969); OTAKAR ODLOZILÍK, *The Hussite King: Bohemia in European Affairs, 1440–1471* (1965); and JAROLD KNOX ZEMAN, *The Anabaptists and the Czech Brethren in Moravia, 1526–1628* (1969). PETER BROCK, *The Political and Social Doctrines of the Unity of Czech Brethren in the Fifteenth and Early Sixteenth Centuries* (1957), remains an important work. The development of modern Czech nationalism and of the Czechoslovak state are explored in JOHN F.N. BRADLEY, *Czech Nationalism in the Nineteenth Century* (1984); PETER BROCK and H. GORDON SKILLING (eds.), *The Czech Renascence of the Nineteenth Century* (1970); STANLEY Z. PECH, *The Czech Revolution of 1848* (1969); JOSEPH F. ZACEK, *Palacký: The Historian as Scholar and Nationalist* (1970); and BARBARA K. REINFELD, *Karel Havlíček (1821–1856): A National Liberation Leader of the Czech Renascence* (1982). The relationship between the Czechs and the Germans is dealt with in ELIZABETH WISKEMANN, *Czechs & Germans: A Study of the Struggle in the Historic Provinces of Bohemia and Moravia,* 2nd ed. (1967); GARY B. COHEN, *The Politics of Ethnic Survival: Germans in Prague, 1861–1914* (1981); F. GREGORY CAMPBELL, *Confrontation in Central Europe: Weimar Germany and Czechoslovakia* (1975); RONALD M. SMELSER, *The Sudeten Problem, 1933–1938: Volkstumspolitik and the Formulation of Nazi Foreign Policy* (1975); and RADOMÍR LUŽA, *The Transfer of the Sudeten Germans: A Study of Czech-German Relations, 1933–1962* (1964). HEINRICH RAUCHBERG, *Der nationale Besitzstand in Böhmen,* 3 vol. (1905), remains the unacknowledged masterpiece on this subject.

History of Slovakia: Discussions of Slovakia include JIŘÍ MUSIL (ed.), *The End of Czechoslovakia* (1995); MINTON GOLDMAN, *Slovakia Since Independence* (1999); and STANISLAV J. KIRSCHBAUM, *A History of Slovakia: A Struggle for Survival* (1995), and *Historical Dictionary of Slovakia* (1999). JOZEF LETTRICH, *History of Modern Slovakia* (1955, reissued 1985), is a standard work up to World War II. Slovak nationalism is covered by PETER BROCK, *The Slovak National Awakening* (1976); JOSEPH A. MIKUŠ, *Slovakia, A Political History: 1918–1950,* rev. ed. (1963; originally published in French, 1955); DOROTHEA H. EL MALLAKH, *The Slovak Autonomy Movement, 1935–1939: A Study in Unrelenting Nationalism* (1979); and CAROL SKALNIK LEFF, *National Conflict in Czechoslovakia: The Making and Remaking of a State, 1918–1987* (1988). (Z.A.B.Z./Mi.Ha./Ed.)

Physical and human geography. General descriptive information on the region is available in MILAN HOLEČEK *et al., The Czech Republic in Brief* (1995), a geographic guide; LIBRARY OF CONGRESS, Federal Research Division, *Czechoslovakia: A Country Study,* 3rd ed., edited by IHOR GAWDIAK (1989); DAVID W. PAUL, *Czechoslovakia: Profile of a Socialist Republic at the Crossroads of Europe* (1981); SHARON L. WOLCHIK, *Czechoslovakia in Transition: Politics, Economics, and Society* (1991); and HANS BRISCH and IVAN VOLGYES (eds.), *Czechoslovakia: The Heritage of Ages Past* (1979), a collection of essays.

The land and the people: Basic geographic information is discussed in JAROMÍR DEMEK *et al., Geography of Czechoslovakia,* trans. from Czech (1971); and VLASTISLAV HÄUFLER, *Ekonomická geografie Československa,* 2nd rev. and enlarged ed. (1984). Works with sections on Czechoslovakia include DEAN S. RUGG, *Eastern Europe* (1985); and ROY E.H. MELLOR, *Eastern Europe: A Geography of the COMECON Countries* (1975). G.Z. FÖLDVARY, *Geology of the Carpathian Region* (1988), includes coverage of much of Slovakia. Useful atlases are JOZEF ŠCIPÁK and JINDŘICH SVOBODA (eds.), *Atlas ČSSR,* 8th ed. (1984); EMIL MAZÚR (ed.), *Atlas Slovenskej socialistickej republiky* (1980), the text of which is available separately in English in EMIL MAZÚR and JOZEF JAKÁL (eds.), *Atlas of the Slovak Socialist Republic* (1983); and *Atlas Životního Prostředí a Zdraví Obyvatelstva ČSFR* (1992), in English and Czech, a survey of environmental conditions and the health of the population. The Gypsies and other minorities are discussed in OTTO ULČ, "Gypsies in Czechoslovakia: A Case of Unfinished Integration," *Eastern European Politics and Societies,* 2(2):306–332 (Spring 1988); DAVID M. CROWE, *A History of the Gypsies of Eastern Europe and Russia* (1996); and PAUL ROBERT MAGOCSI, *The Rusyns of Slovakia: An Historical Survey* (1994).

The economy, administration, and social conditions: Studies of the Czech Republic's economic transformation are VÁCLAV KLAUS, *Renaissance: The Rebirth of Liberty in the Heart of Europe* (1997); JIŘÍ VEČERNÍK, *Markets and People: The Czech Reform Experience in a Comparative Perspective* (1996); MARTIN MYANT (M.R. MYANT) *et al., Successful Transformations?: The Creation of Market Economies in Eastern Germany and the Czech Republic* (1996); J. KŘOVÁK (JIŘÍ KŘOVÁK) (ed.), *Current Economics and Politics of (ex-) Czechoslovakia* (1994); and JAN SVEJNAR (ed.), *The Czech Republic and Economic Transition in Eastern Europe* (1995).

A historical overview is ALICE TEICHOVA, *The Czechoslovak Economy, 1918–1980* (1988). The history of economic reform proposals from 1948 to 1982 is treated in JOHN N. STEVENS, *Czechoslovakia at the Crossroads: The Economic Dilemmas of Communism in Postwar Czechoslovakia* (1985); and MARTIN MYANT, *The Czechoslovak Economy, 1948–1988: The Battle for Economic Reform* (1989). Also useful are the relevant sections in M.C. KASER (ed.), *The Economic History of Eastern Europe, 1919–1975,* 3 vol. (1982–86); FRANK W. CARTER, "Czechoslovakia: Geographical Prospects for Energy, Environment, and Economy," *Geography,* 75(328): 253–255 (July 1990); and two articles in *Communist Economies and Economic Transformation,* vol. 4, no. 1 (1992): MILICA ZARKOVIC BOOKMAN, "Economic Issues Underlying Secession: The Case of Slovenia and Slovakia," pp. 111–134; and JOSHUA CHARAP, KAREL DYBA, and MARTIN KUPKA, "The Reform Process in Czechoslovakia: An Assessment of Recent Developments and Prospects for the Future," pp. 3–22. (F.W.C./Ed.)

Cultural life: MILOSLAV RECHCIGL, JR. (ed.), *The Czechoslovak Contribution to World Culture* (1964), is a historical collection of essays on all aspects of intellectual life, with an extensive bibliography. Czech and Slovak writers and their works are discussed in ROBERT B. PYNSENT and S.I. KANIKOVA (eds.), *Reader's Encyclopedia of Eastern European Literature* (also published as *The Everyman Companion to East European Literature,* 1993). Specific studies of music and folk art include VLADIMÍR ŠTĚPÁNEK and BOHUMIL KARÁSEK, *An Outline of Czech and Slovak Music,* trans. from Czech, 2 vol. (1960–64); ROSA NEWMARCH, *The Music of Czechoslovakia* (1942, reprinted 1978); and VĚRA HASALOVÁ and JAROSLAV VAJDIŠ, *Folk Art of Czechoslovakia,* trans. from Czech (1974), on the art and architecture of both Slovaks and Czechs. (Z.A.B.Z.)

Damascus

Among ancient cities of the world, Damascus is perhaps the oldest continuously inhabited. Its name, Dimashq in Arabic (colloquially ash-Shām, meaning "the northern," as located from Arabia), derives from Dimashka, a word of pre-Semitic etymology, suggesting that the beginnings of Damascus go back to a time before recorded history. Today it is the largest city and capital of the Syrian Arab Republic. Over the centuries, Damascus has been conqueror and conquered, wealthy and destitute, and capital of empire. Its life has been nourished periodically by immigrants from its hinterland and from the Mediterranean Basin and Southwest Asia. Often a focus of contention by powers of East and West, Damascus' fortunes have frequently been linked to those of distant capitals. Now a burgeoning metropolis of the Middle East, it retains, as it has through centuries of triumph and disaster, an indomitable spirit and a not inconsiderable charm.

This article is divided into the following sections:

Physical and human geography

THE LANDSCAPE

The city site. Water and geography have determined the site and role of Damascus. Early settlers were naturally attracted to a place where a river, the Baradā, rising in the Anti-Lebanon Mountains, al-Jabal ash-Sharqī, watered a large and fertile oasis before vanishing into the desert. This tract, al-Ghūṭah, has supported a substantial population for thousands of years. Damascus itself grew on a terrace, 2,250 feet (690 metres) above sea level, overlooking the Baradā River. The original settlement appears to have been situated in the eastern part of the Old City. City and oasis grew together, and over time Damascus came to dominate the lesser settlements near it.

Advantageous location

The natural endowments of an assured water supply and fertile land made Damascus self-sufficient. Its position on the edge of the desert and at the eastern end of the only easy route through the Anti-Lebanon range also made it a trade centre where caravan routes originated and terminated. Also, since the advent of Islām, Damascus has been the starting point of a pilgrimage road, the Darb al-Hajj, to the Muslim holy cities of Arabia.

Climate and vegetation. Some 50 miles (80 kilometres) from the sea, yet separated from it by two mountain ranges, Damascus receives only about seven inches (178 millimetres) of rain annually, most of it from November through February. The Anti-Lebanon range gets far higher amounts of both rain and winter snow, which annually replenish the water table that is a source of the Baradā River. Winter, because of altitude, is rather cold, with average temperatures around 40° to 45° F (5° to 7° C). A short blossoming spring in March and April is followed by six to seven months of hot, dry summer. Temperatures average around 80° F (27° C) in midseason, although they occasionally reach 100° F (38° C) or above. Dust-laden winds blowing in from the desert are somewhat mitigated by small mountain ranges.

Travellers to Damascus have been struck by the sight of aspens and poplars growing along streams, of fruit (particularly apricot) and nut orchards, and of olive groves and vegetable gardens. Ibn Baṭṭūṭah, the Arab travel writer, reaching Damascus in 1326, said that no words could do justice to the city's charm and resorted to quoting his predecessor of more than a century earlier, Ibn Jubayr, that Damascus had "adorned herself with flowers of sweet scented herbs" and "is encircled by gardens as the moon . . . by its halo." A European traveller, Ludolph van Suchem, in 1350 wrote of the city as ". . . begirt with gardens and orchards and watered in and out by waters, rivers, brooks and fountains cunningly arranged to minister to men's luxury . . . ." While the growth of the city since World War II has sharply raised the ratio of buildings to trees and open space, Damascenes still enjoy the parks and gardens of the oasis.

The city layout. The heart of the Old City, that part which contains most of the artifacts of its long history, is a rough oblong about 1,640 yards long and 1,100 yards wide, which is defined by historic walls. The long axis of the oblong runs east and west. Many of its most prominent features owe their positions to the city planners of early Hellenistic times and the Roman builders who followed them.

Classical and medieval development

In the 13 centuries following Damascus' capture by Muslim armies, Islāmic urban life and building have largely obscured the classical remains, whose pavements lie some 15 feet below the present street level. Although the population decreased drastically in the early Middle Ages, by the 13th and 14th centuries Damascus had revived and was outgrowing its walls. Two axes of development predominated—one to the northwest linking the city with the suburb of Ṣālḥīyah on the slopes of Jabal Qāsiyūn; the second growing like a long finger to the south.

The modern city follows a plan devised by the French during the mandate period and revised in the 1960s. Along wide boulevards much new housing has developed in the form of concrete blocks of flats. Government buildings are concentrated in an area west of the walled city around Marjah Square and in several districts west of Ṣālḥīyah Street. Stimulated by the appeal of modern housing and amenities, well-to-do families began in the 1930s to move to the area northwest of the Old City and, subsequently, in other directions. As the population grew, more and more of the garden and farm area was converted to residential districts. Farming villages close by were incorporated into the city, administratively and physically. Government efforts to retain green areas and to zone industry have slowed the loss of gardens and orchards.

THE PEOPLE

Surging population growth

Damascus' population has grown more than sixfold since World War II. It has grown at a rate higher than that of the country as a whole mainly because of migration from rural areas. So heavy has been the influx of migrants drawn by employment and educational opportunity that the average age of the Damascenes dropped below that of the national level. Among the religious minorities, the 'Alawites from the Latakia region are notable for their prominence in government. Other groups maintain their identity among the majority Sunnī Muslim

populace; there are a substantial number of Christians and Palestinians, but the once-flourishing Jewish population has shrunk to a few thousand.

THE ECONOMY

Industry. Government is Damascus' most important economic activity. National politics and administration, including a large military establishment, are centred there. Well known over the centuries for luxurious manufactured wares, especially textiles, the growing city with its work force has attracted many new industries since the mid-20th century. All major factories and most industries are state-run. Textile plants, the chemical industry, and cement works are principally distributed to the south, east, and northeast. Traditional artisan crafts are still practiced, and most of the population's requirements for food, clothing, and the like are sold by private businesses.

Commerce. The historic role of Damascus as a "desert port" has changed because of political developments and the scale of modern commerce. Most imports come through Syria's own ports of Latakia and Bāniyās instead of through Lebanon, as was the case until about the mid-20th century. Goods are transshipped to countries of the Arabian Peninsula, but trade with Iraq ceased after the borders were closed in 1982. Damascus distributes its own products and imported goods within Syria as well. A large international trade exposition is held there in the autumn.

International trade

Transportation. In modern Damascus the internal-combustion engine is superseding horses and donkeys as a means of transport, and camel caravans have vanished from the city scene. Motor vehicles are now the backbone of Damascus' transport system. Buses carry passengers both within the city and to other parts of the country; they are supplemented by the "service"—a car or van that travels an established route for a fare when a full load has been gathered. Major highways fan out in all directions from Damascus, leading to such cities as Beirut, Amman, Baghdad, and Aleppo. A standard-gauge rail line north to Ḥimṣ (Homs), opened in 1983, ties in with the national railroad system; it and the trucking industry bring imported products to the city. Damascus International Airport is about 20 miles east of the city.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. The municipality is administered as a *muḥāfaẓah* (governorate), one of 14 in the country. The president of Syria appoints a governor who administers the city with the assistance of a council made up of elected and appointed members. The post of governor of Damascus is an important one that has national implications. Political activity is national, not municipal, Syria being a centralized state with one party dominating public affairs. The outlying portions of the Ghūtah and a vast surrounding district constitute another governorate, Dimashq, of which Damascus city is the capital.

Services and health. The growing population has put a strain on the city's services and health facilities. Damascus draws its water from a Baradā River source, receiving it through a centuries-old system that has been enlarged several times. Electricity is generated locally and also is brought from the hydroelectric station at the Euphrates Dam. Health care has been improving and is better than in much of the country. About half of the country's doctors practice in the capital, dividing their services between government hospitals and private clinics. The ratio of hospital beds to population has been rising but is still low compared to more industrialized countries.

Improving health care

Education. An extensive public school system provides primary and secondary education for the vast majority of Damascene children. Private schools supplement the public schools, and there is a separate system run by the United Nations for Palestinian refugee children. The University of Damascus, founded in 1923, is the largest and oldest of Syria's four universities, and there are several institutes of technical training.

CULTURAL LIFE

Damascus is Syria's cultural as well as its political centre. Under the Ministry of Culture, which supervises most of the formal aspects of the cultural life of the capital, there is an effort to combine elements of the city's heritage with contemporary developments. The National Museum, charged with preserving the country's past, and the Museum of Popular Arts and Traditions are well attended. An institute for music instructs in both traditional and Western styles; another institute promotes the theatre arts; a third sponsors a performing folklore troupe. The work of Syrian artists and of foreigners is exhibited regularly. Subsidized by the government, however, artistic expression is from time to time impeded by bureaucratic caution. The state dominates publishing, which is centred in Damascus; three national dailies are edited in the city, as are most of the nation's magazines. Damascus also leads the country in book publication, an enterprise that involves the government as the leading publisher.

State regulation of arts

Television enjoys considerable appeal; programming includes locally produced material in addition to imports from other Arab countries and from abroad. Damascus radio broadcasts in Arabic, English, French, Turkish, and other languages. Sports among the Damascenes are growing in popularity. Association football (soccer) especially is becoming a national pastime, and swimming and basketball, along with wrestling, boxing, and tennis, are among other popular recreations. The city's three stadiums draw large crowds for a heavy schedule of events.

History

EARLY CENTURIES

Excavations in 1950 demonstrated that an urban centre existed in the 4th millennium BC at Tall as-Ṣālḥīyah, southeast of Damascus. Pottery from the 3rd millennium BC has been found in the Old City. Before the 2nd millennium BC an intricate system of irrigation for Damascus and al-Ghūṭah had been developed that was augmented by successive rulers through the centuries. Historically, the first written reference to the city is in the hieroglyphic tablets of Tell el-Amarna in Egypt, where "Dimashqa" is listed among conquered territories in the 15th century BC. Biblical sources refer to it as the capital of the Aramaeans, a Semitic people who have left a legacy in portions of the canal system, place-names, and, in one outlying area, the Aramaic language itself. In succeeding centuries before Christ, it fell like other capitals of the Middle East to foreign conquerors—to Assyrians in the 8th century, Babylonians in the 7th, Persians in the 6th, Greeks in the 4th, and Romans in the 1st.

Invasions in ancient times

With Alexander's conquest in 333 BC, Damascus became part of the Hellenistic world for almost a thousand years. The Aramaean quarters coexisted with a new Greek settlement, whose architectural remains may be seen in arcaded streets. Incorporation into the Roman Empire continued the Hellenistic tradition. The citadel in the northwest corner rests on Roman foundations. About 220 yards east of it is the Great Mosque of Damascus, built by the Umayyads on the same site as the Byzantine Church of St. John, the Roman Temple of Jupiter, and the Aramaean sanctuary of Hadad. Still preserved is Ananias (Hanani) Chapel, commemorating the conversion in Damascus of Saul of Tarsus, who became the Apostle St. Paul. It stands near the eastern end of the Street Called Straight (modern Bab Sharqi Street), the classical east–west thoroughfare of the Romans.

With the division of the Roman Empire at the end of the 4th century AD, Damascus became an important military outpost for the Byzantines. Religious and political differences, however, increasingly divided Constantinople from the Syrians. Furthermore, the Persian wars of the 6th century, fought largely on Syrian soil, ruined the economic life of the country. As a result, Damascus opened its gates not unwillingly to the Muslim armies in 635.

THE MUSLIM CITY

Damascus was the first great city of the ancient world that the Muslim Arab forces encountered. In 661, Muʿāwiyah, the first Umayyad caliph, moved out of Arabia and established his court in the Syrian capital. The city was renowned for almost a century thereafter as the capital of

The mosque of Süleyman I, Damascus, with Jabal Qāsiyūn in the background.
Carl Frank

Capital of Islām

a luxurious and extensive empire—the most far-reaching of any achieved by Islām. The principal extant monument of this period is the Great Mosque of Damascus, begun under caliph al-Walīd I in 705. Although it has been damaged, burned, and repaired several times, it is still a glory of Islāmic architecture. On the west wall of the courtyard are the remains of 8th-century mosaics: a golden vision of houses, gardens, streams, and bridges, which has been variously interpreted as a scene of paradise or of Damascus as it then was.

The ʿAbbāsids on coming to power in 750 transferred the capital of the Muslim state east to Baghdad. From that time until the advent of Seljuq Turkish power in the 11th century, Damascus languished in the backwaters of the Muslim world. As ʿAbbāsid power weakened, Damascus and other cities in the region constantly warred with one another. Public order and economic life declined.

During this chaotic period the open plan of the Roman town was modified considerably. With little civic authority city life increasingly centred on quarters where people of common ethnic, religious, or occupational interest lived together: the Muslims in the centre of the city, the Christians to the northeast, and the Jews in the southeast. Behind its barricades, each neighbourhood was thus a minicity under a leader and with its own amenities—mosque, bath, public oven, water supply, and markets. A typical house in the Old City was erected around a courtyard with fountains and trees and showed a blank wall to the street.

Revival under Nureddin

A new era opened when Nureddin (Nūr ad-Dīn ibn Zangī), a powerful Seljuq, captured the city in 1154 and made it once again the capital of a large empire. The town revived; religious buildings were erected, new forms of architecture were introduced, and new quarters for immigrants sprang up. The city continued to flourish under his successors, the Ayyūbids, and their successors, the early Mamlūks, who ruled Egypt and Syria from 1250 until 1382. There were unfortunate interludes when the city was occupied and partially burned by the Mongols. Damascus was the second city—after Cairo—of the Mamlūk Empire, its first line of defense, and the staging point for attacks to drive out crusaders and Mongols. Suqs, or markets, serving the garrisons grew up in the area to the north of the citadel, and suburbs were extended. In the 14th century as many Damascenes lived outside the walls as within. Excess food was exported primarily to the Egyptian capital, and the manufacture of luxury items such as brocaded silks, inlaid metalwork, ceramics, and glass for the conspicuous consumption of the lavish Mamlūk courts and for European markets was encouraged.

For several Islāmic rulers Damascus was a favourite place of residence. Four—Nureddin, Saladin and his brother, al-ʿĀdil, and Baybars I—are interred within the Old City. Their tombs, which are combined with religious colleges, or *madrasahs*, are among the city's most attractive medieval buildings, blending unobtrusively into the urban surroundings. A charming feature is the segmented melon dome that crowns the cupolas. Two of these complexes, the ʿĀdilīyah Madrasah and the aẓ-Ẓāhirīyah Madrasah, face one another across a narrow street and house, respectively, the Arab Academy and the National Library.

Under the later Mamlūks, Damascus suffered from rapacious governors and civil strife among contenders for power. More dire were the pillage of the city in 1401 by Timur (Tamerlane) and his deportation of skilled artisans and workmen to Samarkand. Damascus regained some prosperity in the mid-15th century as corrupt Mamlūk leaders jostled for power. Paradoxically, a lively project of public works continued, but in a more ostentatious fashion than under the Ayyūbids.

Sacking by Timur

OTTOMAN PERIOD

With the Ottoman conquest of Syria in 1516, Damascus lost its political strength yet retained its commercial importance. Treaties opened the Turkish and Syrian ports of the eastern Mediterranean chiefly to the French and later to other nationalities. For Damascus, Sidon (now in Lebanon) was the chief port. Within the city *khans*, or warehouses, proliferated. These handsome stone structures served as hotels for merchants and places for the storage, exchange, and transshipment of goods. By the

18th century the Damascene merchant had reduced the open courtyard of the *khan* and covered it with cupolas to protect the merchandise from the weather. The As'ad Pash Khan (1732) is a notable example.

A second factor in the continuing prosperity of Damascus was the pilgrimage (*ḥajj*) to Mecca and Medina. Annually a great caravan under the command of the pasha of Damascus (the Ottoman governor) left Damascus for the Muslim holy cities. The pilgrims spent weeks provisioning themselves in Damascus before the caravan set out. The city also profited from trade in the merchandise that the pilgrims brought back from Arabia. The Maydān, the southernmost part of the city, was the headquarters for this traffic, which centred around the 16th-century as-Sinānīyah Mosque with its green-tiled minaret.

Between 1831 and 1840 Syria once more came under Egyptian control with the rise of Muḥammad ʿAlī. Europeans were allowed into the city on more lenient terms; foreign schools and missions were established. The restoration of control of Syria from Constantinople was followed by a violent outbreak of religious fanaticism in the 1850s and early 1860s. After Midhat Paşa, the great Ottoman reformer, became governor in 1878, he made civic improvements, widening streets and improving sanitation. In the early 20th century the Damascus–Medina rail line, which shortened the pilgrim's trip to five days, was built by German engineers. During World War I the Syrian capital was the combined headquarters of Ottoman and German forces in their thrust to the Suez Canal and subsequent defensive war against British forces and their Arab allies.

Decline of Turkish rule

Before and during World War I the rise of Arab nationalism found ready ground in Damascus, which became a centre of anti-Ottoman agitation. Fayşal, son of the grand *sharīf* of Mecca, made secret visits there to enlist support for the Arab cause. In a countermove, Jamal Pasha, the Ottoman commander, hanged 21 Arab nationalists on May 6, 1915, a day that is still commemorated. The Ottomans evacuated the city in September 1918.

THE MODERN CITY

With the departure of the Ottomans, Damascus entered a new era, during which it has changed in size, physical appearance, and political role. An independent Syrian state was declared in 1919 with Damascus as its capital; Fayşal was proclaimed king early in 1920. A few months later, the French, with a League of Nations mandate, defeated his army and entered the city. Damascus resisted the French takeover, and an uprising in 1925 was put down only after the French bombarded the city. The years of the French mandate over Syria, from 1920 to 1946, were a period when Damascenes, along with their fellow countrymen, struggled for their nation's independence and for the broader goal of a single Arab state. The Baʿth Party, devoted to that goal, originated there during World War II. The mandate period lasted until April 1946, when, responding to a United Nations resolution, French troops finally left Syria. Once again Damascus was the capital of an independent Syria.

Focus of Syrian politics

Under the republic, Syria's turbulent political life has revolved around Damascus. In this role it has functioned as a pole of attraction for political forces, for economic interests, and for rural people seeking a better life. On several occasions, leadership of the country changed by coup d'état, to the rumble of tanks in the streets. In the 1960s the Baʿth Party came to power in Syria and brought more stability to government.

The city underwent a building boom during the last several decades of the 20th century, when many traditional buildings were replaced with new hotels and shopping centres. The government also implemented a long-term plan to increase tourism to the city.

Contemporary Damascus is a metropolis with many of the features—and problems—found in cities around the world. The physical limits of terrain and finite water sources argue for decentralization to satellite communities some distance away. Were Ibn Baṭṭūṭah, Ibn Jubayr, or other early visitors to return, they would not exclaim so much over a city set in green gardens. They would, however, recognize the spirit and dynamism of the city in the midst of its conversion to a modern metropolis.

The Art of Dance

Dance is the movement of the body in a rhythmic way, usually to music and within a given space, for the purpose of expressing an idea or emotion, releasing energy, or simply taking delight in the movement itself. Dance is a powerful impulse, but the art of dance is that impulse channeled by skillful performers into something that becomes intensely expressive and that may delight spectators who feel no wish to dance themselves. These two concepts of the art of dance—dance as a powerful impulse and dance as a skillfully choreographed art practiced largely by a professional few—are the two most important connecting ideas running through any consideration of the subject. In dance, the connection between the two concepts is stronger than in some other arts, and neither can exist without the other.

Although the above broad definition covers all forms of the art, philosophers and critics throughout history have suggested different definitions of dance that have amounted to little more than descriptions of the kind of dance with which each writer was most familiar. Thus, Aristotle's statement in the *Poetics* that dance is rhythmic movement whose purpose is "to represent men's characters as well as what they do and suffer" refers to the central role that dance played in classical Greek theatre, where the chorus through its movements reenacted the themes of the drama during lyric interludes.

The English ballet master John Weaver, writing in 1721, argued on the other hand that "Dancing is an elegant, and regular movement, harmoniously composed of beautiful Attitudes, and contrasted graceful Posture of the Body, and parts thereof." Weaver's description reflects very clearly the kind of dignified and courtly movement that characterized the ballet of his time, with its highly formalized aesthetics and lack of forceful emotion. The 19th-century French dance historian Gaston Vuillier also emphasized the qualities of grace, harmony, and beauty, distinguishing "true" dance from the crude and spontaneous movements of early man:

> The choreographic art . . . was probably unknown to the earlier ages of humanity. Savage man, wandering in forests, devouring the quivering flesh of his spoils, can have known nothing of those rhythmic postures which reflect sweet and caressing sensations entirely alien to his moods. The nearest approach to such must have been the leaps and bounds, the incoherent gestures, by which he expressed the joys and furies of his brutal life.

John Martin, the 20th-century dance critic, almost ignored the formal aspect of dance in emphasizing its role as a physical expression of inner emotion. In doing so, he betrayed his own sympathy toward the Expressionist school of modern American dance: "At the root of all these varied manifestations of dancing . . . lies the common impulse to resort to movement to externalise states which we cannot externalise by rational means. This is basic dance."

A truly universal definition of dance must, therefore, return to the fundamental principle that dance is an art form or activity that utilizes the body and the range of movement of which the body is capable. Unlike the movements performed in everyday living, dance movements are not directly related to work, travel, or survival. Dance may, of course, be made up of movements associated with these activities, as in the work dances common to many cultures, and it may even accompany such activities. But even in the most practical dances, movements that make up the dance are not reducible to those of straightforward labour; rather, they involve some extra qualities such as self-expression, aesthetic pleasure, and entertainment.

This article discusses the techniques and components of dance as well as the aesthetic principles behind its appreciation as an art. Various types of dance are discussed with emphasis on their style and choreography. The article DANCE, THE HISTORY OF WESTERN covers the history of dance in the West. For information on the character and history of dance in non-Western cultures, see the sections on dance or the performing arts in AFRICAN ARTS; EAST ASIAN ARTS; CENTRAL ASIAN ARTS; SOUTH ASIAN ARTS; ISLĀMIC ARTS; OCEANIC ARTS; and AMERICAN INDIANS. The interaction between dance and other art forms is discussed in MUSICAL FORMS AND GENRES and FOLK ARTS.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 625.

The article is divided into the following sections:

The aesthetics of dance

BASIC MOTIVES: SELF-EXPRESSION AND PHYSICAL RELEASE

One of the most basic motives of dance is the expression and communication of emotion. People—and even certain higher animals—often dance as a way of releasing powerful feelings, such as sudden accesses of high spirits, joy, impatience, or anger. These motive forces can be seen not only in the spontaneous skipping, stamping, and jumping movements often performed in moments of

intense emotion, but also in the more formalized movements of "set" dances, such as tribal war dances or festive folk dances. Here the dance helps to generate emotions as well as release them.

Altered perception of the body and environment

People also dance for the pleasure of experiencing the body and the surrounding environment in new and special ways. Dance often involves movement being taken to an extreme, with, for example, the arms being flung or stretched out, the head lifted back, and the body arched or twisted. Also, it often involves a special effort or stylization, such as high kicks, leaps, or measured walks. Dance movements tend to be organized into a spatial or rhythmic pattern, tracing lines or circles on the ground, following a certain order of steps, or conforming to a pattern of regular accents or stresses.

Barbara Morgan

Children dancing in a spontaneous expression of energy and emotion.

All of these characteristics may produce a state of mind and body that is very different from that of everyday experience. The dance requires unaccustomed patterns of muscular exertion and relaxation as well as an unusually intense or sustained expenditure of energy. The dancer may become intensely aware of the force of gravity and of a state of equilibrium or disequilibrium that normal activities do not generate. At the same time, the dance creates a very different perception of time and space for the dancer: time is marked by the rhythmic ordering of movement and by the duration of the dance, and space is organized around the paths along which the dancer travels or around the shapes made by the body.

Dance can, in fact, create a completely self-contained world for dancers, in which they are capable of physical effort, prowess, and endurance far beyond their normal powers. Ṣūfī dervishes, as an extreme example, can whirl ecstatically for long stretches of time without appearing tired or giddy, and certain Indonesian dancers can strike daggers against their naked chests without causing apparent pain or injury.

This transcendence of the everyday may also be experienced by the spectators. Drawn into the rhythms and patterns created by the dancer's movements, they may begin to share in the emotions being expressed through them. They may also experience kinesthetically something similar to the physical sensations of the dancer. Kinesthesia, or the awareness of the body through sensations in the joints, muscles, and tendons, rather than through visual perception, not only defines the dancer's experience of his own body in movement but also the way in which dance exerts its power over the spectators, who not only see it but also feel an echo of the dancer's movements and rhythms in their own nerve endings.

Kinesthesia and the union of dancer and spectator

PROBLEMS IN DEFINING DANCE

Self-expression and physical release may thus be seen as the two basic motives for dance. Dance itself, however, takes a wide variety of forms, from simple spontaneous activity to formalized art or from a social gathering where everyone participates to a theatrical event with dancers performing before an audience.

Defining according to function. Within this broad spectrum of forms, dance fulfills a number of very different functions, including the religious, the military, and the social. Nearly all cultures have had, or still possess, dances that play an important part in religious ritual. There are dances in which the performers and even the spectators work themselves into a trance in order to transcend their ordinary selves and receive the powers of the gods or, as in the case of Indian temple dancers, in which the performers enact the stories of the gods as a way of worshiping them. In some early Christian communities, processions or formal dance patterns formed part of the prayer service.

It is possible to view modern military marches and drilling procedures as descendants of the tribal war and hunting dances that have also been integral to many cultures. War dances, often using weapons and fighting movements, were used throughout history as a way of training soldiers and preparing them emotionally and spiritually for battle. Many hunting tribes performed dances in which the hunters dressed in animal skins and imitated the movements of their prey, thus acquiring the skills of the animal in question and, through sympathetic magic, gaining power over it.

Dance also plays a number of important social roles in all cultures, notably in matters of celebration, courtship, recreation, and entertainment. Courtship dances, for example, allow the dancers to display their vigour and attractiveness and to engage in socially accepted physical contact between the sexes. (The waltz, a relatively modern example of the courtship dance, was banned at certain times because its flagrant contact between the dancers was considered indecent.) Such traditional dances often contain fertility motifs, where mimed (or even actual) motions of sexual intercourse are enacted. One motif in particular, the fertility leap, in which the male dancer lifts the woman as high as he can, is common to many courtship dances, such as the Tyrolean Schuhplattler.

The importance of dance in courtship and social gatherings is probably older than its use as recreation and entertainment. Many scholars have suggested that dance was once an integral part of everyday life, accompanying both practical activities and religious rituals. Only when more complex social and economic structures began to emerge and a leisured class or caste came into existence did people begin to see dance as a source of pleasure, in some way distinct from the most important issues of survival.

As tribal societies gave way to more complex civilizations, many of the earlier ritual forms, such as religious, work, and hunting dances, gradually lost their original significance and developed into recreational folk dances while still retaining many of their original motifs, such as the use of sticks or swords in the English morris dance or the pole in Maypole dances. All kinds of dance in all stages of evolution, however, have retained some importance as means of social cohesion. Dance has also been used as a means of displaying political or social strength and identity. In ancient Greece, for example, citizens were compelled to attend dance dramas partly in order to encourage allegiance to the city-state. An example in the 19th century was Hungary's purposeful revival of its national dances in order to promote a strong sense of national identity.

Distinguishing dance from other patterned movement. In all the different dance forms, movement becomes dance through stylization and formal organization, an organization that may be variously determined by an aesthetic idea or by the function of the dance (see below *Choreography*). There are, however, many kinds of activities involving disciplined and patterned movement that do not fit the category of dance—for example, sports or the behaviour of certain animals—because the principles that govern these activities are not the crucial principles of aesthetic pleasure, self-expression, and entertainment.

Distinguishing between a wrestling match and a choreographed fight in a ballet can illustrate the importance of these principles in defining dance. It is easy to distinguish between a real fight and a fight in a ballet because the former occurs in "real life" and the latter takes place in a theatre and because in the latter the antagonists do not

actually want to hurt each other. But in wrestling matches, although the antagonists look as if they are fighting, they are also taking part in a choreographed drama that, like the ballet, is partly appraised on questions of style. In the wrestling match, however, these questions of style are not, as in ballet, central to the event but only incidental. The principle most strongly governing the fighters' movements is the scoring of points rather than aesthetic appeal or self-expression. For this reason, even choreographed wrestling matches do not fit the same category as dance. (The martial arts of Southeast Asia cannot be as easily distinguished from dance, because the movements of the practitioners are expected to be as refined and as graceful as those in dance.)

Competition in sports

Ice skating, particularly in its contemporary form of ice dance competition, is more difficult to distinguish from dance, because both aesthetic and expressive qualities are important. But at the same time, there are certain rules that have to be followed more stringently in ice skating than in dance, and once again the governing principle is the competitive display of skills rather than the enjoyment of movement for its own sake. (Dance competitions in which performers are given points present an even more difficult case of distinguishing art from sport, but, to the extent that it is governed by the principle of scoring points, dance competition cannot be defined as art.)

Marches and processions present another difficulty of classification. Some involve patterned groupings of people and a disciplined, stylized movement such as the military goose step, and the participants may feel and express powerful emotions. Such movements also may be accompanied by highly theatrical elements, such as colourful costumes, props, and music, that often accompany dance. But in a march the movement itself is so subordinate to other considerations—such as the mobilization of large numbers of people or the playing of music—that it cannot be regarded as dance.

Defining according to intent. An important factor distinguishing dance from other patterned movement is that of intention. The flight patterns made by swarms of bees or the elaborate courtship rituals of certain birds may be more pleasing to watch and more elaborately organized than the simple, untutored dancing movements of a child. Such patterned movements, however, are not referred to, except analogously, as dances because they are rooted in involuntary genetic behaviour necessary for the survival of the species. In other words, they are not intended as entertainment, aesthetic pleasure, or self-expression. Indeed, it may be argued that for an activity to count as dance, the dancer must be at least capable of distinguishing it as such or must intend it as such. (In a duet by the American choreographer Paul Taylor, two men simply remained motionless on stage for four minutes. Yet the piece was accepted as dance because of its aesthetic context: it was in a theatre and Taylor was known as an experimental choreographer. In addition, the spectators knew that it was intended as a piece that either was dance or was about dance.)

Even when an activity is clearly identified as dancing, there are frequent debates as to whether it is part of the art of dance. Any art form evolves through strong aesthetic principles, and the three main principles governing the art of dance have been discussed above. But of these three principles some may be recognized by one group and not by another. For example, classical ballet reached its zenith in Russia in the late 19th century: Its technique was perfectly developed, and its dancers were acknowledged virtuosos. But a number of choreographers, reacting against the dominant aesthetics of classical ballet, argued that it was simply empty acrobatics and not dance at all because it concentrated on showing the skills of individual dancers and failed to express any significant ideas or emotions. Similarly, when Martha Graham, the pioneer choreographer in American modern dance, first presented her works in the late 1920s, audiences found them so unlike the ballets that they were used to that they refused to acknowledge them as dance (see below *Theatre dance: Modern dance*). The debate goes on over the works of today's avant-garde choreographers, and the same is true for one culture's perceptions of another culture's dance. When Europeans first encountered the highly sophisticated Middle Eastern dance form *raqṣ sharqī*, they perceived it as erotic display and called it the belly dance.

Disagreement over the dominant aesthetic principle

DANCE AS DRAMATIC EXPRESSION OR ABSTRACT FORM

The debate in the West. In Western theatre-dance traditions, notably ballet and modern dance, the most recurrent clash of principles has been over the question of expression. Theatre dance generally falls into two categories: that which is purely formal, or dedicated to the perfection of style and display of skill, and that which is dramatic, or dedicated to the expression of emotion, character, and narrative action. In the early French and Italian ballets of the 16th and 17th centuries, dance was only a part of huge spectacles involving singing, recitation, instrumental music, and elaborate stage design. Although such spectacles were loosely organized around a story or theme, the dance movement itself was largely formal and ornamental, with only a very limited range of mime gestures to convey the action. As dance itself became more virtuosic and ballet began to emerge as a proper theatrical art form, the technical prowess of the dancers became the major focus of interest. Ballet developed into a miscellaneous collection of short pieces inserted, almost at random, into the middle of an opera with no other function than to show off the dancers' skills. In *Lettres sur la danse et sur les ballets* (1760; *Letters on Dancing and Ballets*) Jean-Georges Noverre, the great French choreographer and ballet master, deplored this development. He argued that dance is meaningless unless it has some dramatic and expressive content and that movement should become more natural and accommodate a wider range of expression: "I think . . . this art has remained in its infancy only because its effects have been limited, like those of fireworks designed simply to gratify the eyes. . . . No one has suspected its power of speaking to the heart."

Romantic ballet and dramatic expression

During the great Romantic period of ballet in the first half of the 19th century, Noverre's dream of the ballet d'action was fulfilled as ballet, now a completely independent art form, occupied itself with dramatic themes and emotions. But by the late 19th century the importance attached to virtuosity at the expense of expressiveness had again become an issue. In 1914 the Russian-born choreographer Michel Fokine argued for reform on lines similar to those of Noverre, asserting that "the art of the older ballet turned its back on life and . . . shut itself up in a narrow circle of traditions." Fokine insisted that "dancing and mimetic gesture have no meaning in a ballet unless they serve as an expression of its dramatic action, and they must not be used as a mere divertissement or entertainment, having no connection with the scheme of the whole ballet."

Outside the ballet companies, exponents of modern dance in Europe and the United States were also arguing that ballet expressed nothing of the inner life and emotions, for its stories were childish fantasies and its technique was too artificial to be expressive. Martha Graham, whose commitment to dramatic content was so strong that she often referred to her dance works as dramas, created a new style of movement to express what she saw as the psychological and social condition of modern man: "Life today is nervous, sharp, and zig-zag. It often stops in mid-air. That is what I aim for in my dances. The old balletic forms could not give it voice."

In the decades between the world wars, Graham, Mary Wigman, and Doris Humphrey established the school of Expressionist modern dance, which was characterized by serious subject matter and highly dramatic movement. Other choreographers, such as Merce Cunningham and George Balanchine, argued that such close concern with dramatic expression could hamper the development of dance as an art form. Balanchine argued that "the ballet is such a rich art form that it should not be an illustrator of even the most interesting, even the most meaningful literary primary source. The ballet will speak for itself and about itself." The works of these choreographers emphasized formal structure and development of choreography rather than plot, character, or emotion. Partly as a result

Balanchine and abstract form

of their influence, the "abstract," or plotless, ballet became popular among choreographers during the decades after World War II.

Dance as a nonverbal language. At the centre of much debate have been the questions how dance can express emotions and actions in any detailed way and whether it can be thought of as a kind of language. Cultural conventions partly determine the limits of expression. For example, the classical dance of India has more than 4,000 mudras, or gestures through which the dancer portrays complex actions, emotions, and relationships; these gestures are comprehensible to the audience because they have always been at the centre of Indian life and cultural traditions. In classical ballet, however, the vocabulary of mimed gesture is quite small and is comprehensible to only a few informed spectators, thus considerably limiting its expressive range. Referring to the practical impossibility of communicating, through dance, the complex plots and relationships between characters that are common in the spoken theatre, Balanchine once remarked, "There are no mothers-in-law in ballet."

Martha Swope

While dance cannot communicate specific events or ideas, it is a universal language that can communicate emotions directly and sometimes more powerfully than words. The French poet Stéphane Mallarmé declared that the dancer, "writing with her body, . . . *suggests* things which the written work could *express* only in several paragraphs of dialogue or descriptive prose." Because dance movements are closely related to the gestures of ordinary life, the emotions they express can be immediately understood, partly through a visual appreciation of the gesture and partly through a sympathetic kinesthetic response. Thus, when a dancer leaps, the spectators understand it as a sign of exhilaration, and they feel something of the lifting and tightening sensations that excitement produces in the body. In the same way, if a dancer's body is twisted or contracted, they feel an echo of the knotted sensation of pain.

The immediacy of dance movement

Of course, even the gestures of ordinary life are inherited from cultural conventions. A smile or a wave of the hand can, in certain non-Western cultures, be taken as a sign of aggression rather than welcome. In the same way, how spectators interpret dance movements depends on the context in which those movements occur and on the particular spectator who interprets them. A fall may signify despair in one context, or to one person, and a sinking into ecstasy in another.

The distinction between abstract and expressive dance is also a highly artificial one, becoming a clear distinction in critical theory but certainly not in actual performance. In even the most dramatic and mimetic dance, the movement is highly stylized and subjected to an abstract aesthetic principle. The structure of the piece is determined as much by formal considerations as by the narrative events. On the other hand, even the most abstract work expresses some emotion or character relationship simply because it is performed by people rather than neutral objects, and often the most highly elaborate dance pattern has some representational function.

CHANGES IN ATTITUDE TOWARD DANCE

Critics have argued the question of abstraction and expression largely in relation to theatre dance and also on the assumption that dance is a serious art form. Within recent history, however, this assumption was not always held. In late 19th-century Europe, outside Russia and Denmark, dance was generally regarded as mere entertainment with little aesthetic value. Attitudes to dance both as an art form and as a social activity have, in fact, varied dramatically throughout history. In cultures where it had, or still possesses, religious significance, it is treated with great respect. The ancient Greeks also took dance very seriously, both as an integral part of their drama—which had strong political and social significance—and as part of education. Plato wrote in the *Laws* that "to sing well and to dance well is to be well educated. Noble dances should confer on the student not only health and agility and beauty, but also goodness of the soul and a well-balanced mind." Aristotle believed that dance was useful for "purging the young soul of unseemly emotions and preparing for the worthy enjoyment of leisure."

The Romans generally looked down on dance as effeminate and decadent. The historian Sallust remarked of a citizen's wife that "she played and danced more gracefully than a respectable woman should." The early Christian leaders took a similar view and tried to repress pagan dance customs wherever they could. This action has been attributed to the Christian belief that the body, being the unworthy vessel of the soul, should not be indulged by any kind of sensual pleasure or display. The attitude was not completely dominant, though, and some leaders felt that sober and decent dances could play an important role in religious worship. In the 4th century St. Basil asked, "Could there be anything more blessed than to imitate on earth the ring-dance of the angels?" Processional, circle, and line dances were included in many church services and can still be seen in some services in Toledo and Seville, Spain.

At the time of the Renaissance, when the hold of the church on secular life loosened, dance became popular at court (the church had never been successful at repressing dance among the peasants). It became an essential part of

every courtier's education to be able to dance and move gracefully, and this was a time, too, when many performed in amateur court ballets. In England dancing was so popular among all classes that foreign ambassadors spoke of the people as the "dancing English."

During the 17th century the Puritans were more effective at stamping out the most exuberant and pagan of English dance customs, though among the upper classes it was still considered proper for young children to learn to dance, in order, as the philosopher John Locke put it, to instill "a becoming confidence" in them. In America the hold of the Puritans was even stronger, and many leaders frowned upon any kind of dance, recreational or otherwise, as idle and lascivious. Others saw it as a necessary part of education, providing that it was sober and serious. The most prominent exception to pious disapproval of dance was the Shaker sect, which, while prospering in the United States during the 18th and 19th centuries, developed choreographed dances as part of its worship service. The dances often represented quite complex religious themes. One figure, the wheel within a wheel, which was made up of circles turning in alternate directions around a central chorus of singers, represented the all-embracing nature of the Gospel; the outer ring of dancers represented the ultimate circle of truth, while the central chorus symbolized the harmony and perfection of God that is at the centre of life.

Gradually, dance as a means of physical education and entertainment became more popular in the United States. Folk dancing and social dancing were encouraged, and by the 20th century theatre dance, too, began to lose its disreputable taint.

Certainly in the Western world, dance as an art form has never been as popular as it is today, with a wide range of choreographic styles and genres attracting large audiences. As a form of recreation it has also undergone a massive revival, for while many of the folk traditions have been lost, some have been carefully revived and are widely enjoyed. In Asia and Africa many traditional dances have been transferred from the community, where they were dying out, to the theatre. This has brought about a rapid growth in their popularity, both in their places of origin and in the West, where they attract large audiences and are also studied.

Components of the dance

THE DANCER

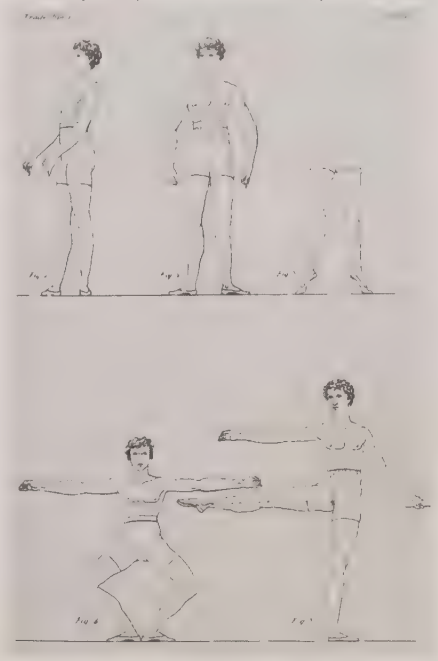
Physical requirements. Dancers are not just performing artists; their bodies are also the instruments through which the art is created. The quality of this art, therefore, necessarily depends on the physical qualities and skills that dancers possess. The stronger and more flexible a dancer's body, the more capable it is of a wide range of movement. Nearly all professional dancers start training at a young age in order to shape and develop their bodies correctly. Strength is built up in the right muscles, for example, and the bone-connecting ligaments on which flexibility of the joints is so dependent are lengthened early before they begin to harden.

As well as strength and mobility, a good dancer must also possess great coordination (the ability to work different parts of the body together), a highly developed kinesthetic awareness (in order to know and control the position and state of the body), control over weight and balance in motion, a developed awareness of space, a strong sense of rhythm, and an appreciation of music. Particularly in dramatic dance, the dancer must be able to project movement clearly and make its expressive qualities intelligible to the audience. Grace, fluidity, and harmony of body are also frequently desired in the dancer, as is physical beauty, but these are subjective qualities that differ from one culture to another and change according to fashion. (Today's physical ideal of the ballerina—long-limbed and slender—is quite different from the late 19th-century preference for a more rounded figure.)

Changing standards of beauty

The importance of training. Though modern avant-garde choreographers sometimes work with untrained dancers to take advantage of the qualities of natural, untutored movement, most dancers in the West are trained either in a strict technique based on classical ballet or in techniques introduced by the 20th-century modern-dance choreographers Martha Graham and Merce Cunningham. (Other kinds of dance, such as jazz or tap, are usually taught in conjunction with these techniques.) Training generally begins early, between eight and 12 years of age for girls and 14 for boys, although some ballet dancers and many more modern dancers begin later. Ballet training closely follows the rules published in 1828 by the Italian dancing master Carlo Blasis in his *Code of Terpsichore.* Blasis advocated at least three hours of dance classes a day, involving exercises that progressively developed different parts of the body.

From Carlo Blasis, *Traite elementaire, theorique, et pratique de l'art de la danse,* by courtesy of the New York Public Library at Lincoln Center



Engravings of ballet positions from *Traité élémentaire, théorique, et pratique de l'art de la danse* (1820) by Carlo Blasis.

Daily classes are necessary not only to mold the body and develop the necessary physical skills but also to maintain the body in its proper condition and prevent injury. Many dance movements make strenuous and unnatural demands on the joints, muscles, and tendons, and it is easy to strain or damage them if the body is not properly maintained. Some bodies are more suitable for training than others, and in the West many aspiring dancers undergo extensive medical scrutiny to ensure that they have no weaknesses or disabilities, such as a weak or crooked spine, that would make them unfit for dancing.

The exercises involved in a dancer's training depend on the style of the dance. Ballet dancers have to work hard to attain a full turnout (the outward rotation of the legs in the hip socket so that the heels touch back to back and the feet form a 180° angle), which enables them to lift their legs high in the air in jumps or arabesques. While ballet dancers rarely use the torso, African dancers and certain modern dancers have to be extraordinarily supple in the torso and pelvis in order to execute the ripples, twists, and percussive thrusts that their particular dances require. Indian classical dancers, while developing great strength and flexibility in the legs, must also achieve great control over the face and neck muscles and flexibility and control in the joints and muscles of the hands. This is necessary to execute their elaborate mudras, conventional symbolic gestures, with accuracy and grace.

Differences among dancers. However rigorous and uniform training may be, each dancer always has a personal style of dancing. Certain skills come more easily to some dancers than to others: one may be an excellent jumper, while another may have exquisite control and balance in

slow, sustained dance passages. The same choreography may also look completely different when executed by two different bodies. Thus, a dancer with very long limbs will make high leg extensions look exaggeratedly long while appearing slightly awkward in fast, intricate footwork. Another dancer may have a great deal of energy and speed but be unable to produce a sustained and beautiful line in held positions.

Finally, dancers vary a great deal in the way they articulate and project movement. Some dancers move in a way that is tense, energetic, and even aggressive in its attack, while others appear soft and fluid. Some phrase their movements so that every detail is sharp and clear; others so that one element flows into another. Some move exactly in time with the phrasing of the music; others phrase their movement slightly independently of it. One dancer may produce movements that are dramatically charged and expressive, while another may be cool and detached, concentrating on technical perfection. Such qualities may vary so markedly that certain dance roles become inextricably connected to the dancers for whom they were created, for example, Anna Pavlova's *Dying Swan,* created by Michel Fokine in 1907, or Rudolf Nureyev and Margot Fonteyn's *Marguerite and Armand,* created by Frederick Ashton in 1963.

In modern dance the dancer may be highly esteemed for individual style and technique but is generally expected to submit his own personality to the demands of the choreography. Some of the works by the American choreographer Alwin Nikolais went so far as to conceal the dancer altogether under a panoply of props, costumes, and lighting projections.

Individuality and conformity

The display of individual style is inevitable in theatre dances such as ballet and modern dance, where trained professionals perform for the pleasure of an audience. Some participatory dances also allow individual dancers to display their talents, as in ballroom or disco dancing, but in many folk dances, particularly those derived from ancient rituals, the sense of unity within the group usually outweighs the importance attached to any one dancer. In primitive religious dance such unity tends to be even more strictly observed. The point of the dance is not the display of the dancer's or choreographer's talents but the perfection of the ritual.

From amateur to professional. Exacting standards and rigorous early training are common where dance has become an art performed before an audience. Such scholars as the German musicologist Curt Sachs have pointed out that in very early cultures, where dance was something in which everyone in the tribe participated, dancers were not regarded as specialists to be singled out and trained because of their particular skills or beauty. Once religious worship (the original occasion for dance) developed into ritual, however, it became important for dancers to be as skilled as possible, for if the ritual was not performed well and accurately, the prayers or magic would not succeed. Dancers were thus selected for special training, which may have taken place either through the family or through skilled individuals who lived and taught outside the community. The dancer's performance now became subject to the most rigorous judgments; indeed, Sachs mentions a tribe on the island of Santa Maria in the New Hebrides (present-day Vanuatu) where, it was said, "old men used to stand by with bows and arrows and shoot at every dancer who made a mistake."

Frequently, in religious dances, the dancer is subjected not only to intense physical training but also to spiritual discipline. Such dancers have often formed a special caste set apart from the rest of the community. In the religious hula dances of Hawaii, the dancers observed important taboos and took part in sacred rites in order to be fit to dance. The traditional religious dancers of India also had to remain pure; they were regarded as brides of the gods and were taught by masters of the highest caste. (Frequently such practices became corrupt, and female temple dancers were also paid to perform in the houses of the wealthy, thus acquiring a reputation for sexual license and promiscuity.)

In Europe professional dance was for many centuries restricted to joculators, wandering bands of jugglers, dancers, poets, and musicians, who were generally regarded as social inferiors. The early ballets were performed almost exclusively by amateur dancers at court (though instructed by professional dancing masters) for whom dance was a means of demonstrating their own grace, dignity, and good manners. The comic, or burlesque, parts alone were performed by professionals, who were not so concerned about their dignity. It was Louis XIV of France, himself an enthusiastic amateur dancer when young, who realized that the art of dance could not advance unless dancers were properly trained professionals. To provide standards for this training, he set up the Académie Royale de Danse in 1661, merging it with the Académie Royale de Musique in 1672. (The Académie survives to the present day as the Paris Opéra Ballet.) Through the work of masters such as Pierre Beauchamps, first director of the Académie Royale de Danse, the main principles of dance technique were codified, and dancers rapidly reached much greater heights of virtuosity. Before Louis's innovations, the split between court dancing, with its carefully cultivated style and patterns of movement, and the less refined peasant dances was already marked, but from this point the gap between professional and amateur dance in Europe really came into being.

BASIC STEPS AND FORMATIONS

Ballet and modern dance. The style and movement vocabulary of classical ballet is rooted in the five turned-out positions of the feet: (1) heels touching and feet forming a straight line; (2) heels apart and feet forming a straight line; (3) one foot in front of the other with the heel against the instep; (4) feet apart, one in front of the other; and (5) one foot in front of the other with the heel against the joint of the big toe. Each of these ballet positions has a corresponding port de bras, or position of the arms and hands.

The five ballet positions

Movements may be grouped into several broad types. First, there are quick, earthbound, linking steps—for example, the pas de bourrée, a flowing step that may be executed in any direction, and the glissade, a gliding step in which the dancer stretches one foot to the side, front, or back, then stretches the other and brings it in to meet the first.

Second, there are jumps, which may be low and light, with the feet battu ("beaten," or crossed rapidly in front of and behind each other several times in midair). In the entrechat, the dancer takes off from the fifth position into a vertical jump. In an assemblé the dancer brushes one foot out to the side, front, or back while springing off of the other; the two feet then come together in midair (where they may be beaten), and the dancer lands in the fifth position. The pas de chat ("step of the cat") is a jump to the side, with first one foot and then the other drawn up beneath the dancer's body before landing in the fifth position. Higher, more vigorous jumps include the grand jeté, in which the dancer throws one leg forward into the air, hovers with the legs stretched to the front and back, and then lands on the front leg, either holding a position such as arabesque or attitude or else closing the back foot into the fifth position.

Arabesque and attitude are positions in which the dancer stands on one leg. In arabesque the other leg (called the working leg) is stretched straight out to the back; in attitude, it is bent and may be extended to either the front or the back.

Turns include the pirouette, which is executed on one leg and on the spot, with the working leg held in a variety of positions, such as attitude, stretched out to the side (*à la seconde*), or with the foot held just above the ankle or at the knee. In the fouetté en tournant the working leg is whipped straight out to the side and then bent in, the foot being brought back to the knee of the supporting leg at each revolution. The piqué is a traveling turn, the dancer stepping out onto the supporting leg before turning on it.

All of these steps may be performed in numerous enchaînements, or combinations, and with the dancers grouped in many different formations. In classical ballet the formations tend to be symmetrical, with circles or lines framing the main dancers at centre stage. Adagio, or

partner work, is crucial to ballet; the man may support the woman in a series of pirouettes or balances and may lift her in many ways. As a general rule, the pas de deux, solo, and group dance alternate fairly regularly, and in the classical pas de deux the two dancers generally separate for individual variations before coming together in a final coda.

Modern dance variations

Modern dance uses many of the steps and positions of classical dance but often in a very different style. The legs may be turned in and the feet flexed or held loosely rather than pointed (see below *Types of dance: modern dance*). There is much greater use of the torso, which may twist, bend, or crouch, and more rolls and falls, in which the dancer works on or close to the floor. Much postmodern dance uses ordinary movements, such as running or walking, as well as simple swinging, spiraling, or stretching movements that involve the entire body.

Folk dance. Many of the steps used in folk dance are like basic versions of ballet steps: small hops and skips; running steps similar to the pas de bourée; and more vigorous steps such as the gallop, in which one leg slides to the front or side and the other leg is brought to meet it in the air with a small spring before the dancer lands on it, ready to slide the original leg forward again. Also common are simple turns, where the dancer pivots on one leg, and lifts, where the man catches his partner around the waist and lifts her into the air. Arm and body movements are usually simple and relaxed, with hands held at the waist or hanging at the sides and the body swaying in rhythm to the movement. In some dances the performers remain separate; in others, they hold hands, link arms, or clasp one another around the waist. Steps are usually repeated in long series, but they often follow quite complex and strictly ordered floor patterns—such as the figure eight, in which the dancers weave around one another. Whether single or in pairs, dancers are usually grouped in circles (often two concentric circles moving at the same time) or lines. Within these groupings there are many specific formations; for example, four or more dancers hold hands and move in a circle, or dancers join hands to form an arch under which the others can pass.

Social dance. Except for display, social dances are rarely performed in any strict formation, although dancers may sometimes form themselves spontaneously into lines or circles. Ballroom dances are categorized instead by their step patterns, rhythms, and tempos. Some of the best-known social dances are the waltz, fox-trot, tango, rumba, samba, and cha-cha. The fox-trot is danced in moderate time, with two steps forward and two steps to the side executed in a slow-slow-quick-quick rhythm. The waltz is a three-step dance, and in the cha-cha five steps are executed in a four-beat measure with a slow-slow-quick-quick-slow rhythm.

The basic step patterns are elaborated by different turns, the dancers pivoting on one foot, as in the waltz, or changing direction while they walk, as in the fox-trot. There are also different kinds of walk—for example, the chassé, in which one foot slides to the front, side, or back, the other slides to meet it, and then the first slides forward again.

The ballroom hold

In many ballroom dances the man and woman remain in the same hold throughout, facing each other or turned slightly to the side. The head may turn and the body sway or bend in response to the rhythm and footwork. In the cha-cha the man and woman may also dance separately. With more freedom to move the body and arms, the hips may sway with the steps and the arms swing rhythmically across the torso.

The basic steps of the original rock and roll dances are performed in the traditional ballroom hold. Dancers may then "break" in order to perform different lifts and turns. For example, the man may hold onto the woman's hand and pivot her under his arm, the woman may jump up with her legs straddling the man's waist, or the man may catch hold of the woman's shoulders and slide her between his legs.

In most later rock dances, from the twist to disco, it is much rarer for people to dance as partners. There is also a greater stress on free arm and body movements than on set patterns of steps. Disco enthusiasts may incorporate elements of jazz, modern dance, and gymnastics into their repertoire, executing high kicks, turns, and even backflips.

CHOREOGRAPHY

Choreography is the art of making dances, the gathering and organization of movement into order and pattern. Most recent works of Western theatre dance have been created by single choreographers, who have been regarded as the authors and owners of their works in a way comparable to writers, composers, and painters. Most social and recreational dances, on the other hand, are products of long evolution, involving innovations that groups of people or anonymous individuals have brought to traditional forms. This evolutionary process is also typical of much non-Western choreography, where both the form and steps of dances are handed down from one generation to another and subject only to gradual and partial change. Even in cultures where it is common for dancers and dancing masters to create their own variations on existing dances, as among the Hopi Indians in northeastern Arizona, it may not be traditional to honour an individual as a particular dance's creator.

Choreographers' motives and methods. When choreographers set out to create new works, or possibly rework traditional dances, their impulses or motivations for doing so vary widely. It may be that a particular dance has a function to fulfill, such as marking a celebration, embellishing an opera, or praying for rain. It may be that the piece has no specific function and that the choreographer is simply responding to an outside stimulus—a piece of music that has suggested a structure or movement, perhaps, or a painting, or a theme from literature, or possibly a particular dancer that the choreographer is interested in working with. Or the stimulus may be the choreographer's desire to express a particular concept or emotion or a fas-

cination with a particular choreographic idea. Such stimuli may, of course, influence the work even if the choreographer is producing it for a specific purpose, though, as with any artist, it is rare that a choreographer's motives and intentions can be clearly analyzed—particularly during the actual working process.

The methods by which different choreographers create their work also vary. Some work closely with the dancers from the beginning, trying out ideas and taking suggestions from the dancers themselves before pulling all of the material together. Others start with clear ideas about the shape of the piece and its content even before going into the studio. The 19th-century choreographer Marius Petipa used small models to work out the groupings of his dances. The amount that any choreographer can do without dancers is limited, because the notation of dance is relatively undeveloped. Whereas a composer can write a complete symphony without meeting the orchestra that is going to play it, dance notation is mostly used in recording rather than creating dances (see below *Dance notation*).

The three-phase choreographic process. The choreographic process may be divided for analytical purposes (the divisions are never distinct in practice) into three phases: gathering together the movement material, developing movements into dance phrases, and creating the final structure of the work.

Gathering the movement material. The way in which the choreographer accumulates movement material depends on the tradition in which he works. In certain dance forms it may be simply a question of creating variations within a traditional pattern of movements. For example, dancing masters in the Italian courts of the 14th and 15th centuries simply invented variations on existing dances and published them in dance manuals bearing their own names. Even today many ballet choreographers use as raw material for their pieces the traditional steps and enchaînements that dancers learn in class. The same is true for many of today's performers of Indian or Middle Eastern dance forms; they may not strictly follow the traditional structure and sequence of movements passed down to them, but they remain faithful to their characteristic styles, retaining the traditional quality of movement and not introducing steps or movements widely different from the original.

Building on tradition

In modern Western forms choreographers have worked less within established traditions, creating instead a vocabulary and style of movement to suit their own personal visions. But even in the work of pioneering choreographers, it is possible to trace major influences. Martha Graham's early work, in the 1920s, for example, was strongly influenced by the American Indian and Southeast Asian dance forms used by her mentor, Ruth Saint Denis. Merce Cunningham's technique owed a great deal to classical ballet. Even Vaslav Nijinsky's ballet *Le Sacre du printemps* (*The Rite of Spring*), which audiences at its first performance in 1913 regarded as a complete break with known dance forms, may have been influenced by the rhythmic-movement exercises of the music teacher Émile Jaques-Dalcroze and by the interest in archaic dance forms already generated by Isadora Duncan and Michel Fokine.

Although each choreographer draws material from diverse sources and often employs contrasting styles, most dance works of a single choreographer show a characteristic style of movement. Dances, however, are rarely if ever a loose collection of isolated movements. One of the most important features of any choreographer's style is the way in which movement material is connected into dance phrases.

Developing movements into phrases. A phrase, loosely speaking, is a series of movements bound together by a physical impulse or line of energy and having a discernible beginning and end. (A rough analogy can be made with the way a singer phrases a multiplicity of notes within a single breath.) Many factors work to make the spectator perceive a series of movements as a phrase. The first is the recognition of some kind of logical connection between the movements that prevents them from appearing arbitrary and isolated. It may be that one movement flows easily and naturally into another within the phrase and that there are no awkward transitions or that there is some clearly visible pattern to the movement (such as the basic three-step phrase in the waltz). Rhythm is a significant factor, and movements are often clearly linked by a recognizable pattern of accents. A movement's accent is measured by its force and duration; thus, a hard, sharp movement has a strong accent, while a soft, gradual movement has a weak one. Even a single movement, such as a head roll, may begin with a strong accent and end with a weak one. In phrases that have perfectly regular rhythm, the strong and weak accents recur in the same sequence and always over the same duration of time.

Dance phrases vary both in length and shape. A phrase may begin with a very forceful movement, or maximum output of energy, that gradually comes to a pause, or it may have its climax somewhere in the middle or at the end. Other dance phrases, in contrast, have an even distribution of energy. These factors determine the way in which the phrase is perceived by, and the effect that it produces on, the spectator. Long, repetitive, evenly paced phrases produce a hypnotic effect, while a series of short phrases with strong climaxes appears nervous and dramatic. One of the distinguishing features of Graham's early style was her elimination of linking steps and fluid transitions between movements, so that many of her dance phrases were short, stark, and forceful.

Effects of various phrases on the spectator

Once a phrase has been constructed, it can be built onto in many different ways. Perhaps the simplest ways are repetition, in which the same phrase is simply repeated, and accumulation, in which the original phrase is repeated with a new phrase added on each time. Separate dance phrases may also be repeated according to a pattern, one of the most basic being the alternation of two phrases, and another being the passing of one or more phrases from one dancer to another in canonic form. Material within a dance phrase can also be developed in a number of ways to create new material. The simplest of these is a straightforward reversal of the sequence of movements in the phrase, but more complex principles of motif and development and of theme and variation are also common. The principle of theme and variation works on the same initial dance phrase being repeated in a number of different ways; for example, with different numbers of people, at different speeds, with different styles of movement (jerky or smooth), or with different dramatic qualities (happy or sad). In motif and development, material from within the phrase is developed in new ways, for example, by embellishing it with other movements (the same jump but with different arm movements), by imitating it on a different scale (the same jump, only bigger or smaller), or by fragmenting it and repeating only small details.

Motif and development, theme and variation

Creating the final structure. The third phase of the choreographic process, creating the overall structure of the dance, may be influenced by a variety of considerations, including the purpose of the dance. If the work is to be a narrative piece, the plot will obviously determine the way in which the dance material is to be structured. It may have to follow a strict succession of events, create characters in a particular order, and bring the drama to climax at the proper moments. Similarly, if the dance forms part of a ritual, the material may have to strictly follow sanctioned form and procedure.

The music determines the structure of a dance work, too—by its length, its arrangement of fast and slow movements, and its treatment of theme. Many of Balanchine's works follow the structure of the accompanying score very closely; this is reflected in pieces with such titles as *Symphony in Three Movements* (1972), set to music by Stravinsky, or *Concerto barocco* (1940), set to music by Bach. Many dance forms actually have the same names as musical forms—such as the rondo, which, by repeating an initial movement in alternation with various contrasting movements, follows the same scheme as its musical counterpart.

A dance's purpose and its musical score are outside influences on its structure. But structure may also be organic; in other words, an entire dance piece may arise from a continuous development of movement ideas, each movement working off of the movement that came before.

Organic development of structure

Richard Alston's *Doublework* (1978), for example, derived its structure from the exploration of the duet form and the repetition of dance material in different contexts. Other movement ideas that may develop in this way are the use of contrasting sections of movement (a section of fast, energetic dancing followed by a slow, meditative passage), the deployment of different numbers and configurations of dancers (a solo followed by an ensemble followed by a trio, and so on), and the manipulation of different floor patterns or different areas of space (a section of leaping movements contrasted with movement executed very close to the ground).

Movement usually develops organically even when the overall structure of the piece is imposed by a plot or piece of music. In the case of narrative ballets, choreographic ideas may develop into formal motifs while still retaining the ability to represent certain actions or situations in the plot. For example, in Ashton's *Fille mal gardée* (1960) ribbons represent the lovers' emotions; tied into a love knot, they signify their passion, and transformed into a skipping rope and cat's cradle, they show their innocence. But at the same time, the ribbons are used in a purely formal way, embellishing certain movements or creating elaborate patterns that can be enjoyed solely for their beauty. In even the most dramatic ballets the representation of emotions and events is heavily stylized, and the ordering of the plot is determined as much by aesthetic as by dramatic logic. Many narrative ballets, like those of Petipa, contain sections of nondramatic dance that develop according to the kind of formal choreographic principles described above.

Finally, the structure of a dance reflects the tradition in which it is created and performed. Ballets in the 19th-century classical tradition tend to last an entire evening and are divided into several acts, with the tragic death or happy marriage of the protagonists occurring at the end. Modern dances are often much shorter, and a single program may include up to a half-dozen pieces. In a performance of the Indian dance form bharata natya, sections of dramatic and abstract dance follow one another in strict succession for a period lasting up to four and a half hours, while in the kathakali dance form of southwestern India, a single performance of alternating dance and music may go on for 16 hours.

DANCE NOTATION

Since dance is a performing art, the survival of any dance work depends either on its being preserved through tradition or on its being written down in some form. Where tradition is continuous and uninterrupted, changes in style and interpretation (inevitable when different dancers perform the same material) may be corrected and the dance preserved in its original form. But when a tradition is broken (if, for instance, the cultural traditions of one ethnic group encroach on those of another), then dances may not only change radically but may even disappear. For this reason methods of recording dance are important in the preservation of its history.

The *Nāṭya-śāstra* and Indian classical dance

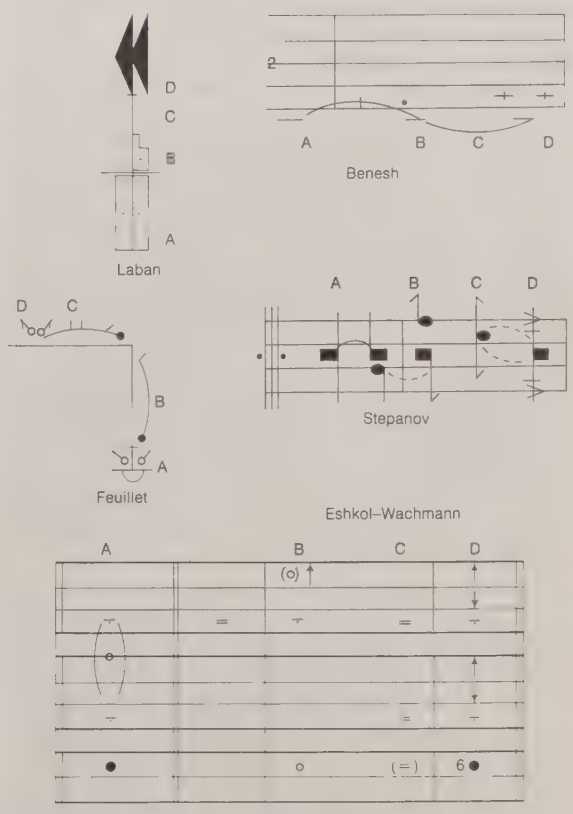
Evidence of dance records dates to the ancient Egyptians, who used hieroglyphs to represent dance movements. In India the earliest book discussing dance, the *Nāṭya-śāstra* ("Treatise on the Dramatic Arts"; variously dated from the 2nd century BC to the 3rd century AD), still survives. This work, which is sacred in Indian culture, codifies dance into a series of rules determining the gestures used to depict different themes and emotions. The bharata natya, a classical dance form based on this treatise, is a good example of a dance tradition that has survived unbroken for many centuries. It only began to founder during the 19th century, partly because Westerners and Indians alike began to deplore its associations with prostitution, but was saved from disappearing altogether when it was developed into a concert form at the beginning of the 20th century. One reason for the long survival of the bharata natya was its importance in religious ceremonies of Hinduism; in addition, when Indian dances were rarely being performed and were in danger of being lost or of degenerating beyond recognition, the *Nāṭya-śāstra* provided a record of traditional principles and styles for their later revival. Even today, not all dance instructors are familiar with these principles, and purists still fear that certain dances are in danger of disappearing or being completely distorted.

Prominent notation methods. The absence in the West of any reliable form of notation until the 20th century resulted in a relative paucity of dance traditions when compared to other art forms. While the music, art, and literature of many centuries past is available today, either in the original or in a reproduced form, there is no complete record of any of the ballets choreographed before the 19th century. Even those works that form the backbone of ballet's classical tradition (*Swan Lake, Giselle,* and *The Sleeping Beauty,* for example) have not survived in forms that fully resemble the original choreography.

During the Renaissance dances were recorded through a simple form of verbal abbreviation, with one letter standing for each individual step—as in B for branle or R for reverence. This method was adequate because the dances of that time were simple and the individual steps were well known. By the 17th century the increasingly complex floor patterns of certain dances, particularly those of the court ballets, led to the emergence of track-drawing systems, the most sophisticated of which was published in 1700 by Raoul-Auger Feuillet in his *Chorégraphie, ou l'art de décrire la danse* ("Choreography, or the Art of Describing the Dance"). Feuillet's work recorded foot positions and combinations of steps as well as floor patterns, but it was unable to register movements in the upper part of the body.

The track-drawing system

Subsequent ballet masters turned to a form of notation using stick figures, the first of which was *La Sténochorégraphie,* published in 1852 by the Frenchman Arthur Saint-Léon. The disadvantage of this system was that it could not record the timing or musical coordination of movements, so that later attempts to produce a system were based on musical notes that would give not only anatomical detail but also the duration of the movement. In the 19th century the most advanced system of this kind was published in *Alphabet des mouvements du corps humain* (1892; *Alphabet of Movements of the Human Body*), by Vladimir Stepanov, a dancer at the Mariinsky Theatre in St. Petersburg (now the Kirov State Academic Theatre



Comparison of five systems of dance notation.
(A) Starting position: stand with feet together. (B) Step forward on the right foot (count 1). (C) Spring into the air. (D) Land to the left, feet together, knees bent (count 2).

of Opera and Ballet in Leningrad). Stepanov's system was used to record many ballets in the Mariinsky's repertoire; the recordings were the basis of subsequent reconstructions of those ballets by the Sadler's Wells Ballet in London.

Stepanov's system still had many disadvantages, one of the most significant being that it was strongly geared toward ballet and could not accommodate the wider range of movements being developed through modern dance techniques. In 1928 Rudolf Laban, a Hungarian dancer, teacher, and choreographer, developed a complex series of principles for analyzing the full range of human movement. His system for recording movements in dance—widely known as Labanotation—had the advantage of being able to record not only the positions of the body and the pattern of the steps but also the way in which movements should be executed (*i.e.*, whether they should be relaxed or forceful and where the accent of the movement should lie).

Labanotation

Choreology, developed by Joan and Rudolf Benesh in 1955, is based on a more clearly visual rather than symbolic form of notation. It is written on a five-line stave, recording the dancer's position as viewed from behind. The top line shows the position of the top of the head; the second, the shoulders; the third, the waist; the fourth, the knees; and the fifth, the feet. Special symbols such as lines, dots, and crosses indicate what each part of the body is doing—for example, whether a limb is straight or flexed and in which direction (to the side or front or in a circle) each part is moving. Other symbols show the quality or dynamics of the movement, its rhythm and accent, and the group formations of the dancers. Choreology is now the most frequently used system, particularly in Britain. In 1958 Noa Eshkol and Abraham Wachmann proposed a mathematical system in which movement (of the joints, for example) was analyzed anatomically, in degrees of circular movement in either positive or negative directions, with positions of the body being fixed in relation to two coordinates.

Video recording is more readily accessible than written notation, though it fails to represent the three-dimensional nature of dance and is unable to record movements when one dancer is concealed behind another. It may be useful when used in tandem with some form of written notation, particularly as it can provide a record of how individual dancers interpret particular roles.

Difficulties of notation. The problem with all systems of dance notation is that few choreographers—and even fewer dancers—are literate in them. As currently practiced, dance notation is mostly used only for the recording, rather than the creating and learning, of dances. Given the present method of creating in the studio, it is impossible for a choreographer to take an overall view of the work; it is difficult to make changes or to experiment in the way a composer can, because the choreographer is limited by the relatively short period of time allowed for rehearsals and by practical considerations such as the dancers' availability and fatigue.

Even the best system of notation cannot succeed completely, because it cannot alter the fundamental nature of dance. Like any other performing art, dance is essentially ephemeral, existing only at the time of its performance. It can never be properly recorded or preserved, since the way in which dancers interpret a work—their styles, technical abilities, and physical appearance—always change the work each time it is performed.

Ephemeral nature of dance

THEATRICAL ELEMENTS

Music, design, and drama have all played important roles in the evolution of dance, and in many cultures dance has actually been inseparable from these arts. The Greek word *mousikē*, for example, referring to music, poetry, and dance as one form, reflected the integral relation between these three arts in classical Greek drama. In the early European ballets, dance, music, drama, and spectacle were equally inseparable.

Even where dance is perceived as an independent art form, most choreography is still accompanied by one or more of these elements. Choreographers generally regard them as integral parts of the works. Sound and visual effects, for example, can clarify the dramatic effect of a dance movement and can also help the spectator to perceive more fully its aesthetic qualities. In a general way, music, design, and drama also work together to heighten the experience of dance as something removed from everyday experience, inspiring a special attention in the spectator.

Rhythm and music. The most important element of dance is music, and it is rare for dance of any kind—social, theatrical, or religious—to develop without musical accompaniment. The close relation between dance and music is based on the fact that both are organized around rhythmic pattern; thus, the rhythm of the accompanying music may be used to determine the rhythm of the dance, to give it emphasis, or to help the dancers maintain the same beat.

Rhythm. Nearly all physical activity is done rhythmically, as in the beating of the heart, the flow of the breath, and the actions of walking and running. Work activities such as digging, sawing, scrubbing, or planting also tend to fall into a regular rhythm, because that is the most efficient and economical way of working the muscles and pacing the effort. When the rhythm is perfectly even, a regular pattern of time and force is established—each inhalation and exhalation of the breath and each stride or stroke of the saw taking the same amount of time and using the same amount of energy. In dance, too, the setting up of regular, efficient rhythms may also be important in allowing the dancer to continue dancing for a long time, whether the dancer be a Ṣūfī dervish or a disco dancer.

Individual dance movements also have a natural rhythm that determines the way in which they can be executed. A high leap, for example, can take only a certain amount of time (the force of gravity preventing a very prolonged duration and the height of the leap precluding a very quick one). Thus, the rhythm, or pattern of accents, imposed on the leap can be neither very sharp nor very sustained.

Even though choreographers are limited to those rhythms permitted by the various dance movements, they do not always use those that are most natural and efficient. It may be easier for a dancer to perform a section of runs and jumps at a moderate, evenly paced rhythm, but this may not produce the effect that the choreographer wants.

Choreographers vary dance rhythms for many reasons, the most basic being the wish to create different qualities of movement—a slow, even rhythm, for example, to create softness and fluidity, or a fast, asymmetrical rhythm to make the movement attenuated or uneven. Varying the qualities of movement may also have a dramatic function, rhythm often determining whether a movement appears joyous, calm, or anguished. Also, choreographers following a musical score may manipulate the rhythms of the dance movements either to match or counterpoint those of the music.

Effects of varying rhythm

Rhythm is a vital element of all dances in all cultures, even in those African and Asian dances whose complex rhythms are often imperceptible to the Western observer. In these forms, the drummer may play a different rhythm with each hand, one setting the basic pulse and the other producing a pattern of sound to reflect the mood or meaning of the dance. The dancer, too, may set up one rhythm in the stamping of the feet while marking out another in the torso, arms, or head, thus producing a highly varied and irregular pattern of sounds and movements. It is rare for dance not to follow any kind of rhythmic organization, just as poets who do not follow a strict metre still emphasize and manipulate the rhythms of language.

Music. Many of the terms used in reference to dance rhythm, such as tempo, dynamics, and beat, are derived from music, as most dance is either set to music or accompanied by it. Particularly in cases where the choreographer sets the dance to a previously composed score, the music may determine both the length and structure of the work and even the exact phrasing of the movements. At its simplest, there may be an exact correspondence between the notes and the dance steps, as in a basic waltz melody. On a more complex scale, as in the music visualization popular with such choreographers as Ruth Saint Denis, dancers or groups of dancers are assigned to

specific instruments and are choreographed in such a manner that they duplicate on stage the relationships among the instruments in the orchestra. Balanchine was said to have translated music into spatial terms, manipulating the floor patterns and the grouping of the dancers so that they corresponded to the appearance and development of particular chord sequences, rhythmic patterns, melodies, or sections of counterpoint. Nijinsky, on the other hand, in *L'Après-midi d'un faune* (1912; *Afternoon of a Faun*), used Debussy's music purely for atmosphere, permitting it to set the mood rather than influence the organization of movements.

Music setting the style and drama

Music can determine the style or dramatic quality of a dance. In fact, composers are often instructed to emphasize or clarify the drama already inherent in the choreography. In Western ballet it is common for important characters to have their own musical themes expressing and identifying their personalities or for whole sections of music to be written in the style of the character dancing to them—as in the sweet, tinkling music that Tchaikovsky composed for the Sugar Plum Fairy in *The Nutcracker*. In plotless dances music and movement also reflect and reinforce each other, as in Ashton's *Monotones* (1965–66), where the clear, uncluttered lines of the choreography reflect the limpidity of Satie's music.

Certain choreographers in the second half of the 20th century have worked either without music or in such a way that music and dance remain wholly independent of each other. Merce Cunningham choreographed in silence, so that while the music helped to determine the overall mood of the dance, it rarely affected the dance's phrasing and structure and often did not even last for the same length of time. Cunningham believed that too close a correspondence between dance and music would not really help the audience to perceive the two forms more clearly but, rather, would have the opposite effect of each canceling the other out. Other choreographers, such as Jerome Robbins in *Moves* (1959), used complete silence even in performance, so that the natural sounds of the dance movements formed the only accompaniment, leaving the spectator to concentrate solely on the patterns and rhythms of the movement. Others have used natural or electronic sounds and even spoken words in an effort to separate dance from a close relationship with music while still providing it with some relationship to sound.

Union of dance and music. It is likely that music accompanied dance from earliest times, either through sounds such as stamping, clapping, and singing that the dancers made themselves, through percussion, or through various wind instruments such as pipes or flutes. In modern Afro-Caribbean dances it is possible to discern the effects that drumming and percussive-sounding movements can have on dancing—in maintaining the dancer's beat, providing accompaniment, and intensifying the dance's emotional power. A slow, heavy beat can create a mood of tension or expectancy, while a fast beat may build the dance to a joyous or dramatic climax. The rhythms of the drums, reinforced by clapping and stamping, can amplify the rhythms of the movements (the sway of the pelvis, the rippling of the spine) as well as set up a complex counterpoint with them to produce variations in tempo and phrasing.

Clapping and stamping can also play an important role in producing the hypnotic effect necessary to certain ritual dances, uniting both spectators and dancers in a single world of sound and clearing their minds of everyday preoccupations. In the war and hunting dances of many tribes, sound is often used in an imitative way, with the dancers uttering war cries or animal sounds in order to further their transformation into warriors or the hunters' prey.

In many Indian and Asian classical dances, stamping also plays an important role in maintaining the beat. Music, too, is very important, and many dances are accompanied by specific songs or musical compositions. In the Middle Eastern *raqṣ sharqī*, the song or music establishes the mood or narrative situation of the dance, which the performer then interprets through movement. In the Indian bharata natya the dancer is accompanied by a singer, who marks the movements with a tiny pair of cymbals while singing out instructions to the dancer. Bells tied around the dancer's ankles also accompany the movements with their sound. Just as in Western theatre dance, the music accompanying these different dance forms is important both for its dramatic function—emphasizing moments of climax or different emotional states—and for its ability to increase the spectator's pleasure in and awareness of the movement.

Music enhancing awareness of movement

Social dance is nearly always accompanied by music, which not only helps to keep the dancers in time with each other but also increases the power and excitement of the dance, encouraging the dancers to abandon themselves to their movements. Sometimes individual dances have developed in response to a new musical form, as in jazz and rock and roll; but dance has also had an important influence on music, as in the Renaissance, when musicians were required to produce music to accompany the new dances that were developing.

Choreographers and composers alike often feel limited and frustrated when they have to create their own works within the limits of someone else's artistic conception. The most fruitful relationship is often one in which an element of collaboration exists between composer and choreographer from the start. Fokine's collaboration with Stravinsky on *The Firebird* (1910) is an example of both score and choreography emerging from long and detailed discussion, during which each artist remained sensitive to the other's wishes and to the overall idea of the work. There are no rules, however, and while some choreographers dislike being subjected to the limitations and demands of a musical score, others regard them as important creative stimuli.

Most dances have a traditional relationship with particular musical works or with particular kinds of music. Although ballet has always had a close relation to classical (as opposed to popular) music, many people have found unacceptable its use of established masterpieces that were not specially composed for ballet. It was not until the 20th century that this practice came into being, with Isadora Duncan performing to Wagner, Brahms, and Chopin and Léonide Massine choreographing his symphonic ballets to the works of Berlioz, Brahms, and Tchaikovsky.

During the 20th century a close relationship has also existed between modern dance and contemporary music, often music of a highly experimental nature. Thus, choreographers have used, or even commissioned, works from composers such as Schoenberg, Webern, Berio, Copland, and Cage. But it is common for both contemporary ballet and modern dance to use a variety of musical forms: modern dance may use early classical or non-Western music, while ballet may be performed to popular music. Also, as mentioned above, the concept of musical accompaniment has been stretched to include any kind of natural sound, electronic score, spoken text, or even silence.

Set and design. Just as music can enhance the mood of a dance and influence the way in which the spectator interprets its dramatic content, so visual elements such as costume, makeup, masks, props, lighting, and stage sets may also amplify certain qualities of dance movement. Because set and design are vital elements of theatre, they are most important in those types of theatre dance, whether dramatic or abstract, in which dancers perform before nonparticipating spectators. Therefore, most discussion of the use of visual elements in dance centres on theatre dance.

Such visual elements as costume and makeup do play a role in participatory social and ritual dances, however. In most war and hunting dances the participants not only imitate the movements of warriors or prey but also use weapons, masks, makeup, and animal skins to heighten the realism of the dance. The wearing of animal skins is a common means in many such dances to magically acquire the animals' strength or agility—hence the eagle feathers worn in the headdresses of many North American Indians or the deerskin shoes traditionally worn by the Scots.

In other ritual dances the dancers' clothes may well possess magical or religious significance. The Ṣūfī dancer begins his ritual by divesting himself of a black cloak that is symbolic of the tomb. Body painting in symbolic colours is characteristic of many tribal dances as a means of keeping away evil spirits, while the embroidery on a

number of European national costumes is often a relic from the days when it functioned as a magic charm. Most important of all, the wearing of special clothes in ritual dances, as in rituals not involving dance, is a way of signaling and preserving the sacred quality of the occasion and removing it from ordinary life.

In festive dances, too, clothes and ornamentation play an important role in embellishing the movement and heightening the atmosphere of gaiety, pomp, or excitement. Social dances frequently have special clothes associated with them—such as the evening suits and voluminous sequined dresses of ballroom dancing or the tight, black clothes of rock and roll. Such clothes are not only the fashion of the era but also the uniform that identifies the dancer more strongly with the dance and the other dancers. Like music, clothes can help dancers surrender their everyday selves to the dance.

Makeup and costume in Indian classical dance

In theatre dances everywhere, the use of visual effects is crucial to the power of the dance. In the Indian kathakali, facial makeup is central to the portrayal of character. Differently coloured beards are used to represent good or bad characters, while the colour of the makeup is even more revealing: a green and red painted face represents an evil and ferocious character, a green and white face is for heroes and noblemen, a pinkish-yellow face is for women characters and sages, and black and red makeup is used for female demons.

The bharata natya dancer relies more purely on the mudras for character portrayal, but makeup and costume are still highly important. The graceful, sinuous lines of the dancer's movements are emphasized by the bare torso and flowing skirt or trousers, while the intricate detail of the mudras is reflected in the rich jewels, flowers, and decoration of the costume.

Costume and stage sets in Western theatre dance. Masks have also been used as a means of characterization in many dance forms, from ancient Egypt to the early European court ballets. One reason early ballet dancers were limited in their dance technique was that the masks they wore to represent different characters were so elaborate and their wigs and clothes so heavy that it was scarcely possible to jump or to move across the floor with any speed or lightness.

The early ballets not only had elaborate costumes but also were performed in spectacular settings. *The Mountain Ballet,* performed in the early 17th century, had five enormous mountains as its stage scenery, in the middle of which was a "Field of Glory." The dance historian Gaston Vuillier later described the scene:

> Fame opened the ballet and explained its subject. Disguised as an old woman she rode an ass and carried a wooden trumpet. Then the mountains opened their sides, and quadrilles of dancers came out, in flesh coloured attire, having bellows in their hands, led by the nymph Echo, wearing bells for headdresses, and on their bodies lesser bells, and carrying drums. Falsehood hobbled forward on a wooden leg, with masks hung over his coat, and a dark lantern in his hand.

It was even known for ballets to be staged outdoors, with mock sea battles staged on artificial lakes.

Gradually, as dancers shed their encumbering costumes and stage designs were simplified, dance movement and mime became more important in the depiction of plot and character. Set design and costume were tailored to the ballet's theme and atmosphere, rather than swamping the choreography with their elaborate opulence. The development of gas lighting meant that magical effects could be created with simple painted scenery, and though wire contraptions were sometimes used to fly the ballerina (as a sylph or bird) across the stage, the development of pointe work (dancing on the toes) meant that the dancer could appear weightless and ethereal without any artificial aids. In place of highly decorative mythological or classical scenes, there were poetic evocations of landscape, and the ballerinas were either dressed in simple white dresses or in colourful national dress. The poet, critic, and librettist Théophile Gautier described the typical "white" or ethereal Romantic ballet as follows:

> The twelve marble and gold houses of the Olympians were relegated to the dust of the storehouse and only the romantic forests and valleys lit by the charming German moonlight of Heinrich Heine's ballads exist. . . . This new style brought a great abuse of white gauze, of tulle and tarlatans and shadows melted into mist through transparent dresses. White was almost the only colour used.

Fokine and the unity of dance and design

This unity of dance and design was not to last, however. By the end of the 19th century most of the productions mounted at the Mariinsky Theatre in St. Petersburg were lavish spectacles in which set and costume had little relevance to the ballet's theme, being designed simply to please the audiences' taste for opulence. At the beginning of the 20th century one of the first revolutionary steps that Michel Fokine took in trying to change this state of affairs was to dress his dancers in costumes as nearly authentic as possible—for example, by replacing the prevailing tutu

with clinging draperies (as in the Egyptian costumes for *Eunice* [1908]) and by dispensing with the dancers' shoes. (Actually, the theatre management did not allow dancers to go barefoot, but they had red toenails painted onto their tights to achieve the same impression.)

This move was part of Fokine's general commitment to the idea that movement, music, and design should be integrated into an aesthetic and dramatic whole. His collaboration with designers such as Léon Bakst and Alexandre Benois were as important as his musical collaboration with Stravinsky. Sets and costumes not only reflected the period in which the ballet was set but also helped to create the dramatic mood or atmosphere—as in *Le Spectre de la rose* (1911; "The Spirit of the Rose"), where the exquisite rose-petaled costume of the spectre, or spirit, seemed almost to emit a magical perfume, and where the simple naturalism of the sleeping girl's bedroom emphasized her dreaming innocence.

In the newly emerging modern dance, experiments with set, lighting, and costume design were also significant. One of the pioneers in this field was Loie Fuller, a solo dancer whose performances in the 1890s and early 1900s consisted of very simple movements with complex visual effects. Swathing herself in yards of diaphanous material, she created elaborate shapes and transformed herself into a variety of magical phenomena. These illusions were enhanced by coloured lights and slide projections playing across the floating material.

Elaborate lighting and costumes were also used by Ruth Saint Denis, whose dances frequently evoked ancient and exotic cultures. At the opposite extreme Martha Graham, who began her career as a dancer with Saint Denis' company, strove to eliminate all unnecessary ornamentation in her designs. Costumes were made out of simple jersey and cut along stark lines that clearly revealed the dancers' movements. Simple but dramatic lighting suggested the mood of the piece. Graham also pioneered the use of sculpture in dance works, replacing painted scenery and elaborate props with simple, free-standing structures. These had a number of functions: suggesting, often symbolically, the place or theme of the work; creating new levels and areas of stage space; and also illuminating the overall design of the piece.

Modern trend toward minimal visual effects

While it has remained common for choreographers to use elaborately realistic sets and costumes, as in Kenneth MacMillan's *Romeo and Juliet* in 1965, most choreographers have tended to adopt a minimal approach, with costumes and scenery simply suggesting the ballet's characters and location rather than representing them in detail. One reason for this development has been the move away from narrative to plotless, or formal, works in both ballet and modern dance, where there is no longer any need for visual effects to provide narrative background. Balanchine set many of his works on a bare stage with the dancers dressed only in practice costumes, feeling that this would allow the spectators to see the lines and patterns of the dancers' movements more clearly.

Effects of design in theatre-dance performance. Set, costume, and lighting design are important in narrative as well as formal dance in helping the audience maintain the special attention that theatre demands. They can also influence strongly the way in which the choreography is perceived, either by creating a mood (sombre or festive, depending on the colour and ornamentation used) or by strengthening a choreographic image or concept. In Richard Alston's *Wildlife* (1984) the geometrically shaped kites suspended from the flies actually inspired some of

the dancers' sharply angled movements as well as making them visually more striking in performance.

Costume, set design, and the perception of movement

Costume, too, can alter the appearance of movement: a skirt can give fuller volume to turns or to high leg extensions, while a close-fitting leotard reveals every detail of the body's movements. Some choreographers, trying to emphasize the nontheatrical or nonspectacular aspects of dance, have dressed their dancers in ordinary street clothes in order to give a neutral, everyday look to their movements, and they have often dispensed entirely with set and lighting.

Set design and lighting (or their absence) can help to frame the choreography and to define the space in which it appears. The space in which a dance occurs has, in fact, a crucial influence on the way movement is perceived. Thus, a small space can make the movement look bigger (and possibly more cramped and urgent), while a large space can lessen its scale and possibly make it appear more remote. Similarly, a cluttered stage, or one with only a few lighted areas, may make the dance appear compressed, even fragmented, while a clearly lighted, open space may make the movement appear unconfined. Two choreographers who have been most innovative in their use of set and lighting are Alwin Nikolais and Merce Cunningham. The former has used props, lighting, and costumes to create a world of strange, often inhuman shapes—as in his *Sanctum* (1964). The latter has often worked with sets that almost dominate the dancing, either by filling the stage with a clutter of objects (some of which are simply things taken from the outside world, such as cushions, television sets, chairs, or bits of clothing) or—as in *Walkaround Time* (1968)—by using elaborate constructions around which the dance takes place, often partly concealed. As with his use of music, Cunningham's sets have often been conceived independently of the choreography and are used to create a complex visual field rather than to reflect the dancing.

Separating dance from everyday life

Perhaps the most important influence on the way spectators perceive dance is the place in which it is performed. Religious dances usually take place within sacred buildings or on sacred ground, thus preserving their spiritual character. Most theatre dance also occurs in a special building or venue, heightening the audience's sense that it has entered a different world. Most venues create some kind of separation between the dancers and the audience in order to intensify this illusion. A theatre with a proscenium stage, in which an arch separates the stage from the auditorium, creates a marked distance. Performance in the round, in which the dancers are surrounded by spectators on all sides, probably lessens both the distance and the illusion. In dance forms that do not traditionally take place in a theatre, such as Afro-Caribbean dance, the intimacy between audience and dancer is very close, and the former may often be called upon to participate.

The theatre space not only influences the relationship between the audience and the dancer but is also closely related to the style of the choreography. Thus, in the early court ballets, spectators sat on three sides of the dancers, often looking down at the stage, because the intricate floor patterns woven by the dancers, rather than their individual steps, were important. Once ballet was introduced into the theatre, however, dance had to develop in such a way that it could be appreciated from a single, frontal perspective. This is one reason turned-out positions were emphasized and extended, for they allowed the dancer to appear completely open to the spectators and, in particular, to move sideways gracefully without having to turn away from them in profile.

Many modern choreographers, wishing to present dance as part of ordinary life and to challenge the way in which people look at it, have used a variety of nontheatrical venues to dispel the illusion or glamour of the performance. Choreographers such as Meredith Monk, Trisha Brown, and Twyla Tharp, working in the 1960s and '70s, performed dances in parks, streets, museums, and galleries, often without publicity or without a viewing charge. In this way dance was meant to "happen" among the people instead of in a special context. Even the most surprising or nonglamorous venue, however, cannot entirely dispel the sense of distance between dancer and audience and between dance and ordinary life.

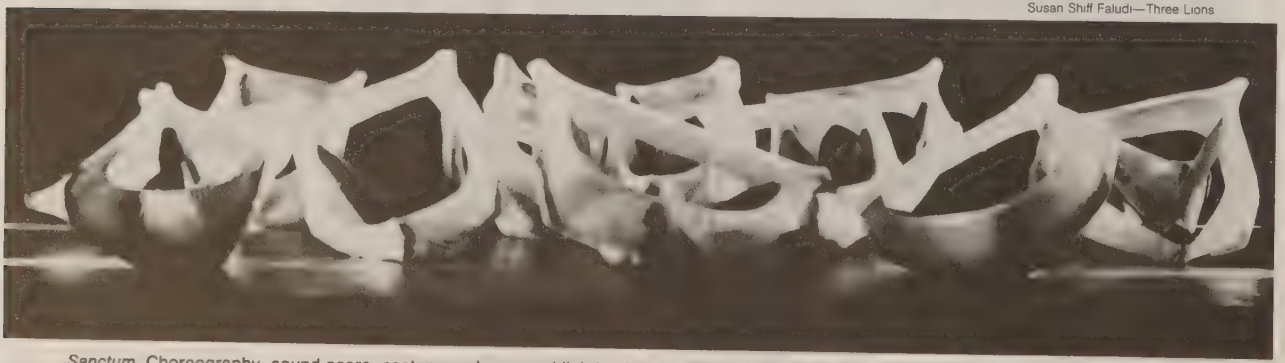
Drama. Throughout history there has been a rough division between dramatic dance, which expresses or imitates emotion, character, and narrative action, and purely formal dance, which stresses the lines and patterns of movement itself (see above *Dance as dramatic expression or abstract form*). The type and function of dramatic dance vary considerably, including full-length theatrical works (in which dance is used to tell a story and present specific characters), hunting dances (in which the dancers' movements imitate those of a particular animal), and courtship dances (which may contain only a few pantomimic gestures, such as a lift, a curtsy, or a mock kiss, to convey meaning).

The expressive quality of dance movement

Because dance movements are often closely related to everyday forms of physical expression, there is an expressive quality inherent in nearly all dancing. This quality is used extensively in dramatic dance to communicate action or emotion—for example, the aggression in stamping movements, the exhilaration communicated by jumping, and the dragging motions of despair. Mime, or narrative gesture, is also used. Mime can either imitate movement realistically—in a death scene, for example, where the killer assumes a ferocious expression and imitates strangling a victim—or it can function as a symbol—as in the circling movement of the arms in ballet to represent dancing or in pointing to the fourth finger to represent marriage. Dance movements are often accompanied by other elements, such as masks, costume, music, acting, singing, recitation, and even film, to help communicate the dramatic content.

Cultural distinction between dramatic and formal dance. Curt Sachs argued that the division between dramatic and formal dance in tribal cultures followed the division between hunting and planter cultures. While the accuracy of his claim may be hard to establish, it can help to illuminate the different types and function of dance that lie at the root of such a division. In hunting dances (and war dances as well) the dancers' movements are dramatically charged, expressing a state of excitement or aggression and frequently imitating the movements of animals or fighting men, even to the point of manipulating weapons.

Susan Shiff Faludi—Three Lions



Sanctum. Choreography, sound score, costumes, decor, and lighting by Alwin Nikolais; Alwin Nikolais Dance Company.

Imitative sounds increase the power of the illusion, as does the wearing of masks, makeup, or animal skins. The effect on both dancer and spectator is to be drawn into a fictional world, in which the dancers become the people or animals that they represent and the story or situation enacted by the dance takes on an immediate reality. Any successful dramatic dance should, in fact, produce this effect, even if the dancers do not actually feel the emotions they are representing or the spectators respond as if the imitation were real.

In the dances of planter cultures, Sachs argued, the movements tend to be smaller and not directly imitative. The groupings of the dancers and the floor patterns traced by their steps, on the other hand, tend to be much more complex and ordered. In addition, the sequence of movements tends to be more repetitive and the dancers' movements are more uniform. Such formal dances are often performed as part of a ritual propitiation of the gods in order to assure good weather and successful harvests. Although their movements may not be imitative, the repetitive patterns often represent such natural occurrences as the cycle of the seasons, the waxing and waning of the Moon, and the growing of vegetation, and they even evoke more abstract entities such as space and time.

Effects of formal dance movement

The effect may thus be one of fusing the dancers and spectators with some aspect of the natural world. At the same time the dance may produce an effect similar to the repetitive chanting of prayer or meditation, emptying the mind of its usual preoccupations and focusing it on the object of worship. In fact, the power of dance in achieving this type of spiritual discipline is peculiarly strong, since the repetitive movements work kinesthetically as well as aurally and visually. As a consequence, mind and body are equally absorbed into the ritual.

Even where formal dances are not part of a ritual (as in modern plotless dance works), the movement of the dancers may produce an effect not dissimilar to that described above. Space, time, and the force of gravity may be made apparent to the spectator through the trajectories that the dancers make in space, through the configurations that they form on the dance floor, through the duration of the dance phrases, and through the alternating sensations of weight and weightlessness created by falls and jumps. In a similar way, too, the audience may experience a special focusing of attention, a draining of the usual habits of perception through the kinesthetic, visual, and aural power of the movement and music.

Many extant tribal dances can be categorized as either imitative or formal, as can the European folk dances that developed out of earlier tribal dance forms. Courtship dances, the descendants of ancient courtship and fertility dances, still retain overt imitations of flirtatiousness. Other dances have similarly retained their early formal character, even, in some cases, retaining the symbolic significance of their patterns. In Ukrainian dances descended from pagan Moon-worshiping ritual, the circling of the dancers represents the way the Moon influences the work in the fields, and the final pivot represents the flourishing of the corn. In Armenian carpet-weaving dances, the complex floor patterns mimic the action of the work process.

Drama in Western theatre dance. When dance developed into a form of spectacle, particularly of a secular kind, it was frequently allied to the telling of a story and the depiction of characters. Mimed gesture was often prominent in such dance dramas—for example, in ancient Greece, where the gestures of the chorus illustrated the drama's major themes. There the mime was often naturalistic: a hand on the head to represent grief or the stretching upward of the arms to express worship. During the later, cosmopolitan period of the Roman Empire, dance and mime were popular entertainment for audiences drawn from a variety of linguistic backgrounds. The highly sophisticated pantomime used by these dancers formed the basis of the improvised mime drama of the 16th-century Italian commedia dell'arte and, later, the techniques of 20th-century mime artists such as Marcel Marceau.

The early European court ballets were also oriented toward dramatic spectacle, though the dance movement itself was not highly expressive and mimed gesture was limited. Other dramatic elements, usually visual effects or speech, communicated the essential points of the story. One of the first choreographers to extend dance movement so that it could be dramatically expressive was the Englishman John Weaver, who in his ballet *The Loves of Mars and Venus* (1717) experimented with giving the characters gestures to express their individual personalities. Later in the 18th century Jean-Georges Noverre reacted against the purely decorative form into which ballet had developed. He believed that mime should be as close to natural gesture as possible and that dance movement should not be meaninglessly decorative but should reflect the ballet's action.

Mime in ballet

Noverre's ideas were partly realized in the Romantic ballet of the early 19th century, which strove to give movement a greater poetic expressiveness. Developments in dance technique, notably that of dancing *en pointe*, gave dancers a wider range of movement to express character and action, although conventional or symbolic mime was also used to tell parts of the story. By the end of the century, however, choreography was once again seldom concerned with plot and character, and long sections of mime (often incomprehensible even to the dancers) were used to tell whatever story there was in the dance. The reforms proposed by Fokine at the beginning of the 20th century, like those of Noverre two centuries before, demanded more naturally expressive mime and dance movement that illuminated theme and character and were an essential component of the dance.

Fokine's own work reflected these ideas faithfully. He experimented with angular movement reminiscent of archaic Greece in *Daphnis et Chloé* (1912; *Daphnis and Chloe*), developed individual styles for different characters (such as the jerky wooden movements of the puppet Petrushka), and brought mime much closer to natural gesture than the symbolic code previously used. This naturalism still characterizes ballet; the expressive qualities of dance movement and simple, dramatic gestures almost entirely displace conventional mime, and even in revivals of the 19th-century classics, traditional mime is usually kept to a minimum so that audiences have no trouble following it.

The founders of modern dance, Isadora Duncan, Mary Wigman, Martha Graham, and Doris Humphrey, also reacted against the lack of expression in ballet. Like Fokine, they believed that most ballet dancing was mere decorative acrobatics, but while Fokine was happy to continue using exotic or archaic themes for his new, naturalistic ballets, these later choreographers believed that dance should address subjects of greater relevance and profundity. The kinds of movement with which the modern dance choreographers expressed these themes had little of conventional ballet technique about them. Eschewing mime, particularly that associated with ballet, as well as

the traditional ballet vocabulary, they sought to make the whole body dramatically expressive. (See below *Theatre dance: Modern dance.*)

During the 20th century, ballet, like modern dance, moved toward a concern with more serious issues. In works such as Antony Tudor's *Jardin aux lilas* (1936; *The Lilac Garden*), Peter Darrell's *Prisoners* (1957), Gerald Arpino's *Clowns* (1968), and Kenneth MacMillan's *My Brother, My Sisters* (1978), choreographers engaged subject matter ranging from emotional and psychological conflict to war and social issues.

The avant-garde

In the avant-garde dance of the 1970s and '80s, experiments were made in expanding narrative potential by incorporating nondance elements (almost turning full circle back to the early court ballets). At times dance was accompanied by mime, acting, and singing as well as a multitude of visual effects. In some cases choreographers collaborated with artists working in other forms, such as music, drama, and the visual arts, and they thought of dance less as a single discipline than as a broadly based theatre art. Most of these experimental works had some kind of dramatic or conceptual content, although they avoided conventional forms of narration and expression. Events were rarely presented in chronological order, and the distinction between reality, symbolism, and fantasy was often blurred.

Types of dance

The division of dance into types can be made on many different grounds. Function (*e.g.,* theatrical, religious, recreational) is an obvious ground, but distinctions can also be made between tribal, ethnic, and folk dance, between amateur and professional, and above all between different genres and styles.

Defining genre and style

Genre and style are relatively ambiguous terms. They depend on analyses of movement style, structure, and performance context (*i.e.,* where the dance is performed, who is watching, and who is dancing) as well as on a cluster of general cultural attitudes concerning the role and value of dance in society. Genre usually refers to a self-contained formal tradition such as ballet, within which there may be further subgenres, such as classical and modern ballet. (Some critics consider modern dance as an independent genre with a subgenre of postmodern dance, but others subsume both categories under ballet, along with other theatre dance forms such as jazz.) Within subgenres, different styles can be distinguished, such as those of Ashton, MacMillan, and Balanchine in modern ballet and Graham and Cunningham in modern dance. Style as used here embraces many elements, including a preference for certain kinds of movement (fast, slow, simple, or intricate) or for particular kinds of energy and attack (sharp, edgy, and hard, as opposed to soft and fluid). It also embraces different ways of phrasing movement or of arranging dancers into groups, as well as an interest in certain kinds of music or design.

Perhaps the most obvious division between types is that between theatre and non-theatre dance. The separation of dancer and spectator in theatre dance has tremendous influence on the style of the dance itself and on its reception as an art form. In theatre dance the professionalism of dancer and choreographer, the presentation of dramatic and formal movement, the use of visual effects, and even the philosophical question of the role of the spectator reach their most sophisticated level. In non-theatre dance the unity of dancer and spectator, of observation and participation, means that the dance styles and even the function within the social group are quite different from those of theatre dance.

Of course, the division between the two types is not as clear in practice as in theory. For example, although ethnic and folk dances are not, in theory, theatre dances, many of them are preserved, choreographed, and presented to audiences in theatrical settings. Some scholars have even argued that ballet is an ethnic dance form that grew out of the European dance tradition. On the other hand, Indian and Southeast Asian dance forms are usually called ethnic dances, but within these traditions there are numerous classical dances whose theatrical settings and elaborate choreographies qualify them as theatre dances.

Among the theatre dances, this section discusses the two major Western genres, ballet and modern dance, as well as Indian classical dance. Among the non-theatre dance forms, this section discusses tribal and ethnic dance, folk dance, and social dance.

THEATRE DANCE

Ballet. *Basic characteristics.* Ballet has been the dominant genre in Western theatre dance since its development as an independent form in the 17th century, and its characteristic style of movement is still based on the positions and steps developed in the court dances of the 16th and 17th centuries (see above *Basic steps and formations*). Perhaps the most basic feature of the ballet style is the turned-out position of the legs and feet, in which the legs are rotated in the hip socket to an angle of 90 degrees and the feet point outward. This position gives the body an open, symmetrical appearance, and it also facilitates the high leg extensions and fast turns typical of ballet. Openness is most characteristic of the ballet dancer's stance, for the head is nearly always lifted and the arms held out in extended curves. Even when the dancer executes fast or energetic steps, the arms rarely move in a way that is not fluid, calm, and gracefully extended, and they are frequently held in positions that either frame the face or form a harmonious relation to the position of the legs. The body is nearly always held erect, apart from controlled arches in the back or a slight turning of the shoulders toward or away from the working leg. This positioning of the shoulders, called épaulement, gives a sculpted, three-dimensional quality to the dancer's positions.

The open stance

Whenever the ballet dancer's foot is not flat on the floor, it is pointed, and, of course, women dancers (and occasionally men) frequently dance on the tips of their toes with the aid of blocked shoes. Dancing *en pointe* lends lightness and airiness to the dancer's movements, and the pointed toe extends the line of the leg—particularly when it is raised in the air, as in an arabesque.

The long vertical line is the other basic feature of ballet: verticality in the upright stance of the body, in the high leg extensions, and above all in the aerial quality of the movement. Ballet dancers rarely move close to the ground, and they frequently seem to defy gravity through the height of their jumps and their vigorous batterie (beating together of the legs in midair), through the speed and multiplicity of their turns, and through the fast linking steps that seem to move them effortlessly, almost without touching the floor, from one virtuoso movement to another. In ballet the stress and effort of the dancer's movements are always concealed beneath the fluid, graceful surface of the dance

The vertical line

and the perfect repose of the face and torso. This gives the dance its characteristic qualities of dignity and control, which it inherited from the early court ballets, where the movements were designed to show off the aristocratic polish of the dancers.

Ballet has, of course, undergone many stylistic alterations. The Romantic style of the early to mid-19th century was much softer—less studded with virtuosic jumps and turns—than the classical style of the late 19th and early 20th centuries. Russian ballet, frequently regarded as the paradigm of the classical school, is itself a blend of the soft and decorative French school, the more brittle and virtuosic style of the Italians, and the vigorous athleticism of Russian folk dances.

The design of classical ballet is traditionally symmetrical in the shapes made by the dancers' bodies, in the grouping of the dancers on stage, and even in the structure of the whole dance. For example, if two principal dancers perform a pas de deux (a dance for two), other dancers on stage remain still, are arranged in symmetrical framing patterns, or move in harmony with the main dancing, not distracting from it. Even when large groups of dancers move, they are usually arranged in formal lines or circles. Jean-Georges Noverre in the 18th century and Michel Fokine in the first decades of the 20th both argued that this kind of formal symmetry was detrimental to the dramatic naturalism of ballet. Fokine's own choreography encouraged the use of less rigid and artificial groupings in later ballet, as in Kenneth MacMillan's dramatic works, where the crowd scenes are often composed of asymmetrical groups that rarely seem artificial.

Innovations in the 20th century. Fokine's reforms were a major influence on the development of 20th-century ballet. Particularly in the works that he created for Sergey Diaghilev's company, the Ballets Russes, he showed the range of different dance styles that classical ballet was capable of absorbing, helping to pave the way for more radical innovation. For example, in *Chopiniana* (1908; later called *Les Sylphides*), a virtually plotless ballet that recalled the earlier Romantic tradition, Fokine created a soft and uncluttered style that contained no bravura feats of jumping, turning, or batterie. Arm movements were simple and unaffected, the grouping of the dancers had a fluid, plastic quality, and above all there was a flowing, lyrical line in the phrasing and movement.

Fokine's non-ornamental style

In *Prince Igor* (1909) and *L'Oiseau de feu* (1910; *The Firebird*) Fokine incorporated the vigorous style and athletic steps of Russian folk dances. These works revealed his talent for organizing large crowds of dancers on stage and transforming their previously ornamental function into a powerful dramatic force. Neither ballet is longer than a single act, because Fokine believed that the full-length ballet was generally both an excuse for, and the cause of, useless choreographic padding, and that a work should last only as long as its theme required.

For all its stylistic variations, Fokine's choreography was couched largely in the classical idiom. Two other choreographers working with the Ballets Russes, Vaslav Nijinsky and his sister Bronislava Nijinska, produced works of a more radical nature. In *Jeux* (1913; "Games"), Nijinsky was one of the first choreographers to introduce a modern theme and modern design into ballet. Based on his own (rather erroneous) idea of a tennis match, the choreography incorporated sporting movements and dancers in modern dress. In *The Rite of Spring,* perhaps Nijinsky's most innovative work, the dancers were arranged in massed groupings and executed harsh, primitive movements, the legs turned in, the arms hanging heavily, and the heads lolling to one side. Unlike Fokine, Nijinsky was prepared to risk ugliness in his search for a truly authentic style, and the audiences were almost as deeply shocked by the choreography as by the discordant sounds and jagged rhythms of Stravinsky's score.

Nijinsky's *Rite of Spring*

In her ballet *Les Noces* (1923; "The Wedding"), which took its theme from the marriage ceremonies of Russian peasants, Nijinska created a stark and heavily weighted style of movement. There were few elevations, and the dancers were frequently crouched or bent over, with their heads hanging low to the floor. They were also arranged in large groups, so that the overall impression was less that of individual bodies moving together than of large shapes and blocks of movement.

Although there are similarities between the works of these choreographers and the modern-dance forms that emerged in the 1920s and '30s, there is little evidence to suggest any direct influence. The major significance of Fokine, Nijinsky, and Nijinska was in their bringing ballet out of its remote, courtly past by using modern themes and subjects and by introducing modern intellectual and artistic influences into the classical art form.

The style of later 20th-century ballet was influenced not only by the Ballets Russes but by modern dance as well. It became common for choreographers to extend the traditional ballet vocabulary with modern-dance techniques, such as curving and tilting the body away from the vertical line, working on or close to the floor, and using turned-in leg positions and flexed feet. Balanchine, influenced by jazz, used syncopated rhythms in his phrasing and incorporated steps from such popular dances as ragtime and rock and roll. His movements were usually wide, almost exaggerated in shape and volume, and frequently characterized by speed and by hard, clear accents.

Influence of other genres

Despite these changes ballet retains significant traces of its courtly and classical past. Although there are exceptions, such as those noted above, ballet dancers still tend to dance in the calm, erect, and dignified manner of their aristocratic forebears. Illusion and spectacle remain important; nearly all works are performed on a proscenium stage in a large theatre, where the performers are distanced from the audience, and productions are frequently elaborate and expensive. Ballet companies still, therefore, tend to be large organizations, receiving some kind of patronage or state subsidy.

Modern dance. *Expressionism.* Modern dance, the other major genre of Western theatre dance, developed in the early 20th century as a series of reactions against what detractors saw as the limited, artificial style of movement of ballet and its frivolous subject matter. Perhaps the greatest pioneer in modern dance was Isadora Duncan. She believed that ballet technique distorted the natural movement of the body, that it "separated the gymnastic movements of the body completely from the mind," and that it made dancers move like "articulated puppets" from the base of the spine. Duncan worked with simple movements and natural rhythms, finding her inspiration in the movements of nature—particularly the wind and waves—as well as in the dance forms that she had studied in antique sculpture. Elements that were most characteristic of her dancing included lifted, far-flung arm positions, an ecstatically lifted head, unconstrained leaps, strides, and skips, and, above all, strong, flowing rhythms in which one movement melted into the next. Her costumes, too, were unconstrained; she danced barefoot and uncorseted in simple, flowing tunics, with only the simplest props and lighting effects to frame her movements.

The style of Isadora Duncan

Duncan believed that dance should be the "divine expression" of the human spirit, and this concern with the inner motivation of dance characterized all early modern choreographers. They presented characters and situations that broke the romantic, fairy-tale surface of contemporary ballet and explored the primitive instincts, the conflicts and passions of man's inner self. To this end they sought to develop a style of movement that was more natural and more expressive than ballet. Martha Graham, for example, saw the back, and particularly the pelvis, as the centre of all movement, and many of her most characteristic movements originated from a powerful spiral, arch, or curve in the back. Doris Humphrey saw all human movement as a transition between fall (when the body is off-balance) and recovery (when it returns to a balanced state), and in many of her movements the weight of the body was always just off-centre, falling and being caught.

Instead of defying gravity, as in ballet, modern dancers emphasized their own weight. Even their jumps and high extensions looked as if they were only momentarily escaping from the downward pull of the Earth, and many of their movements were executed close to, or on, the floor. Graham developed a wide repertoire of falls, for example,

Emphasizing gravity

and Mary Wigman's style was characterized by kneeling or crouching, the head often dropped and the arms rarely lifted high into the air.

As ballet sought to conceal or defy the force of gravity, so it also strove to conceal the strain of dancing. Modern dance, on the other hand—particularly the work of Graham—emphasized those qualities. In the jagged phrases, angular limbs, clenched fists, and flexed feet, in the forceful movements of the back and the clear lines of tension running through the movement, Graham's choreography expressed not only the struggle of the dancer against physical limitations but also the power of passion and frustration. Movements were always expressive gestures, never decorative shapes. Often the body and limbs appeared racked and contorted by emotion, for these choreographers, like Nijinsky, were not afraid to appear ugly (as indeed they did to many of their contemporaries).

The structure of early modern dance works responded in part to the fragmented narrative and symbolism characteristic of modernist art and literature. Graham often employed flashback techniques and shifting time scales, as in *Clytemnestra* (1958), or used different dancers to portray different facets of a single character, as in *Seraphic Dialogue* (1955). Groups of dancers formed sculptural wholes, often to represent social or psychological forces, and there was little of the hierarchical division between principals and corps de ballet that operated in ballet.

Merce Cunningham. The Expressionist school dominated modern dance for several decades. From the 1940s onward, however, there was a growing reaction against Expressionism spearheaded by Merce Cunningham. Cunningham wanted to create dance that was about itself—about the kinds of movement of which the human body is capable and about rhythm, phrasing, and structure. Above all, he wanted to create dance that was not subservient to the demands of either narrative or emotional expression. This did not mean that Cunningham wanted to make dance subservient to music or design; on the contrary, though many of his works were collaborations, in the sense that music and design formed a strong part of the total effect, these elements were often conceived—and worked—independently of the actual dance. Cunningham believed that movement should define its own space and set its own rhythms, rather than be influenced by the set and the music. He also felt that it was more interesting and challenging for the spectator to be confronted with these independently functioning elements and then to choose for himself how to relate them to one another.

Cunningham's balletic style

Believing that all movement was potential dance material, Cunningham developed a style that embraced an extraordinarily wide spectrum, from natural, everyday actions such as sitting down and walking to virtuosic dance movements. Elements of his style even had a close affinity to ballet: jumps tended to be light and airy, the footwork fleet and intricate, and the leg extensions high and controlled. He placed greater emphasis on the vertical and less emphasis on the body's weight and the force of gravity. Like those of Graham, many of Cunningham's movements centred on the back and torso, but they tended less toward dramatic contractions and spirals than toward smaller and more sharply defined tilts, curves, and twists. The arms were frequently held in graceful curves and the feet pointed.

Cunningham's phrases were often composed of elaborate, coordinating movements of the head, feet, body, and limbs in a string of rapidly changing positions. The arrangement of performers on stage was equally complex: at any one moment there might have been several dancers, in what seemed like random groupings, all performing different phrases at the same time. With no main action dominating the stage, the spectator was free to focus on any part of the dance.

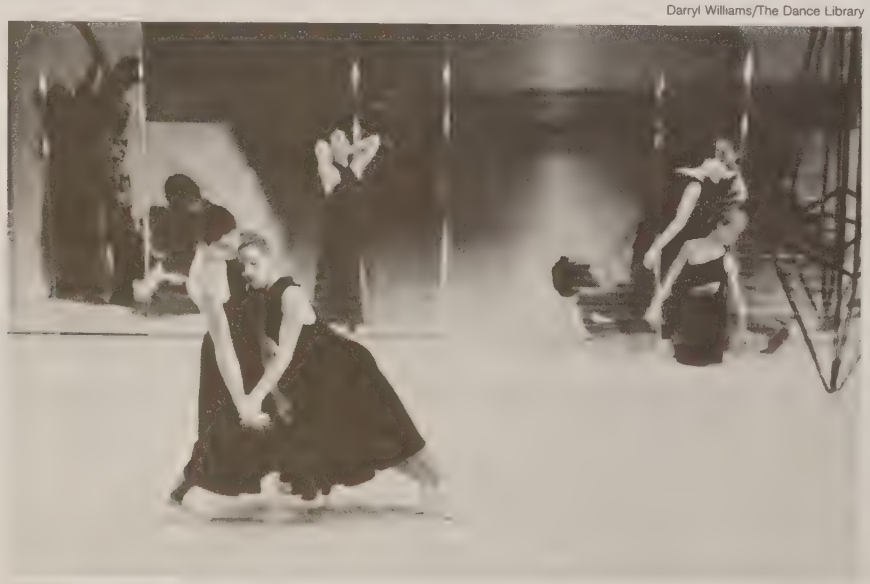
While Graham's works were usually structured around the events of a narrative, Cunningham's works usually emerged from the working through of one or more choreographic ideas, whose development (*i.e.*, the ordering of movements into phrases or the number of dancers working at any one time) might then have been determined by chance. Deriving its movements from such formal origins did not mean that Cunningham's works lacked expressive power. One of his pieces, *Winterbranch* (1964), started out as a study based on moving into a space and falling, but it produced a powerful effect on audiences, who variously interpreted it as a piece about war, concentration camps, or even sea storms. Cunningham believed that the expressive qualities in dance should not be determined by a story line but should simply rise out of movement itself. "The emotion will appear when the movement is danced," he claimed, "because that is where the life is."

Postmodernism. During the 1960s and '70s a new generation of American choreographers, generally referred to as postmodernist choreographers, took some of Cunningham's ideas even farther. They also believed that ordinary movement could be used in dance, but they rejected the strong element of virtuosity in Cunningham's technique and the complexities of his phrasing and structure, insisting that such a style interfered with the process of seeing and feeling the movement clearly. Consequently, the postmodernists replaced conventional dance steps with simple movements such as rolling, walking, skipping, and running. Their works concentrated on the basic principles of dance: space, time, and the weight and energy of the dancer's body.

The focus on movement

Postmodernists discarded spectacle as another distraction

Darryl Williams/The Dance Library



Silent Partners, a modern dance choreographed by Siobhan Davies, 1984; the Siobhan Davies dance troupe performing.

from the real business of movement. Costumes were often ordinary practice or street clothes, there was little or no set and lighting, and many performances took place in lofts, galleries, or out-of-doors. Narrative and expression were discarded, and the dance structures were usually very simple, involving either the repetition and accumulation of simple phrases or the working through of simple movement games or tasks. In Tom Johnson's *Running Out of Breath* (1976) the dancer simply ran around the stage reciting a text until he ran out of breath.

Most avant-garde modern-dance companies have been quite small and have occupied a position on the fringe of the dance world, attracting only small and specialist audiences. Although "mainstream" modern dance now attracts large audiences in both Europe and North America, it too was for many decades a minority art form, often playing to only a handful of spectators. Modern-dance companies were then, and still are, relatively small. Partly because they lack funding, they tend to use less elaborate costume and staging, and they perform in small theatres where contact with the audience is close.

The musical. Perhaps the most genuinely popular of all the subgenres within ballet and modern dance are the dance forms associated with the musical, such as tap, jazz, ballroom, and disco. In musicals of both stage and screen, dance is an essential ingredient along with song, acting, and spectacle. Although the dancing is often mechanical and unoriginal, in the work of such dancers and choreographers as Fred Astaire and Gene Kelly it can rise to the status of a genuine art form. Sometimes, as in Jerome Robbins' choreography for the dances of the rival gangs in *West Side Story* (1957), it creates a powerful dramatic effect. Other innovative choreographers include Agnes deMille, whose dances in *Oklahoma!* (1943) were the first ever used to advance the plot, and Bob Fosse, particularly known for his work on the film *All That Jazz* (1979).

Indian classical dance. The six recognized schools of Indian classical dance developed as a part of religious ritual in which dancers worshiped the gods by telling stories about their lives and exploits. Three main components form the basis of these dances. They are natya, the dramatic element of the dance (*i.e.*, the imitation of character); nritta, pure dance, in which the rhythms and phrases of the music are reflected in the decorative movements of the hands and body and in the stamping of the feet; and nritya, the portrayal of mood through facial expression, hand gesture, and position of the legs and feet.

The style of movement in Indian classical dance is very different from that of Western ballet. In ballet the emphasis is frequently on the action of the legs—in jumps, turns, and fast traveling steps, which create ballet's characteristic qualities of height, speed, and lightness—while the body itself remains relatively still and the arms simply frame the face or balance the body. In Indian dance, however, the legs are usually bent, with the feet flat rather than lifted and pointed. Jumps are usually low (though light), and the dancer rarely covers much ground or performs intricate steps, the complexity of the footwork lying more in elaborate stamping rhythms. (These stamping rhythms enhance the musicality of the dance; many dancers wear bells around their ankles, supplying their own accompaniment as well as counterpoint to the rhythms beaten out by the musicians.) The torso, face, arms, and hands are extremely active. The head is quite mobile, with subtle changes of direction and a characteristic side-to-side movement emphasizing the dancer's changing facial expressions. The movement of the torso is graceful and fluid, shifting from side to side or turning on the axis of the spine, while the movement of the hands and arms is subtle and elaborate, every gesture having a narrative function. Indian dancers have a vast repertoire of gestures through which they express complex events, ideas, and emotions. There are, for example, 13 gestures of the head, 36 different glances, and 67 mudras, or hand gestures, that can, in various combinations, yield several thousand different meanings.

Differences from Western ballet

While these qualities characterize Indian classical dance in general, there are significant variations in each school. Bharata natya is perhaps the most delicate and elegant of

Sitakumari giving the Nataraja, God of Dance, pose in the style of bharata natya, one of the principal Indian classical dance forms.
Nick Sidle/The Dance Library

all the forms. It is traditionally, though not exclusively, performed by women. In the dancer's typical stance the legs are bent, often turned out at the hips, and the body is held upright. Even in movements where the torso bends or spirals, it remains lifted, never dropped and heavy. The feet perform small stamping movements against the ground; for example, the heel may be lifted and the leg extended to the front or back and then brought back. This is a small movement at some points and at others a larger lunge, but none of the steps travels far off the spot. Stamping movements are also made by raising the foot, bringing it down on the ball, and then bringing down the heel. These quick, shifting steps maintain a complex rhythmic relationship with the musical accompaniment. Sometimes such steps include a light spring from one foot to the other.

While the feet are executing the basic step sequence, the arms, hands, and head are also performing intricate movements. The arms are always supported at the elbow, never loosely hanging, and they may be stretched to the side or above the head or bent at the elbows in many different positions. In executing the mudras, the hands convey different meanings according to the position of the fingers and the way the palms are cupped or splayed. The neck moves from side to side, the head nods or turns, the eyes dart and glance in different directions, and the body tilts or leans. Each of these different movements contributes to the rhythmic and visual complexity of the dance.

Kathakali is a dance-drama performed by men, as it is considered too vigorous and difficult for women (although women may study it and perform certain extracts). The dancers wear elaborate headdresses and costumes as well as extensive makeup. The makeup can take up to four hours to apply and allows the dancer to absorb himself in the role he is about to perform. The basic kathakali stance is a deep bend, with the legs turned in and the feet resting on the outside of the soles, giving the dancer a bandy-legged look. This position allows him to survive the long performances without getting sore feet.

Much kathakali dancing is vigorous. The stamping steps are larger and more energetic than in bharata natya, the legs are lifted higher, the lunges are deeper, and the jumps are bigger. Generally the dancers travel farther and with greater agility. The arm, body, and head movements are also more dramatically expressive: the body crouches and twists furiously, the arms make larger, more imitative gestures (as in fight scenes), and the facial expressions are highly exaggerated. (Kathakali dancers have such control over their facial muscles that they can laugh with one side of their faces and cry with the other.) Mudras also help dramatize the story, although they do not always signify the same things as in bharata natya.

Orissi and manipuri use more sinuous movement, in which the spine and torso are elegantly curved. The most characteristic element in kathak is the *chukra,* a brilliant, whipping turn executed on the spot. In this style the feet work closely together, often with one crossed in front of the other and stamping out unusually complex rhythms. The dancer also uses a gliding walk similar to the pas de bourrée in ballet. There is more swaying of the body in kathak than in bharata natya, and the wearing of a full skirt emphasizes the speed and excitement of the dancer's turns.

The influence of Indian dance can be seen throughout Asia. In Japan, for example, the dancer makes use of a fan to create an additional repertoire of gestures. It may be opened to suggest the reading of a book, whirled and dropped to the ground to show the falling of leaves, or, appearing above the dancer's sleeve, used to signify that the Moon has risen. In Java the dancers' faces remain impassive, but their hand gestures are elaborate, and they also manipulate long, floating scarves to give their movements a weightless, ethereal quality.

TRIBAL AND ETHNIC DANCE

Ballet, modern dance, and Indian classical dance are forms of theatre dance, the dancers usually being highly trained professionals performing for audiences in particular venues and on special occasions. Tribal and ethnic dance, on the other hand, may be characterized by a number of almost opposite features. They are not necessarily the province of trained specialists (although they may be); such dances may be participatory (*i.e.,* with no real distinction between dancer and spectator); and while they may take place in special venues or on special occasions, these are often intimately related to the everyday life of the community.

Tribal dance. A tribal society is essentially a self-contained system. While it may possess sophisticated cultural and social structures, its technological and economic structures are generally primitive. Consequently, by the late 20th century such societies had become increasingly rare, and many tribal dances had either died or become transformed.

Some tribal dances have been preserved, however, even in cases where tribes have been absorbed into other social structures, as a means of preserving cultural identity and a sense of historical continuity. This is quite common in many African states. A frequently cited case is that of King Sobhuza II, the Ngwenyama ("Lion") of Swaziland, who in 1966 joined his people in a six-day *Incwala,* or ritual ceremony. Dressed in animal skins and elaborate plumage, Sobhuza performed dances that would ensure the renewal of the land, the king, and the people.

In extant tribal societies, such as the Hopi Indians of northeastern Arizona, dance retains most of its traditional form and significance. The Hopi still dance as a form of worship, with specific dances for different ceremonies. Such dances, however, as in any other tradition, have undergone inevitable change and development throughout history, and they cannot be used as accurate evidence of what the tribal dances of early man were like. Generalizing about tribal dance is made difficult not only by the lack of evidence concerning its origins and the rapid dying of extant forms but also by the fact that the term tribal covers so many different kinds of dance. Tribal dances not only vary from one tribe to another but also fall into many different categories, such as weapon dances, fertility dances, Sun and Moon worshiping dances, initiation dances, war dances, and hunting dances.

Difficulty of defining tribal dance

The following are two examples of tribal dance that have survived into the 20th century. The musicologist Curt Sachs quoted a description of the fertility dance of the Cobéua Indians of Brazil:

> The dancers have large [artificial] phalli . . . which they hold close to their bodies with both hands. Stamping with the right foot and singing, they dance . . . with the upper parts of their bodies bent forwards. Suddenly they jump wildly along with violent coitus motions and loud groans. . . . Thus they carry

> the fertility into every corner of the houses . . . ; they jump among the women, young and old, who disperse shrieking and laughing; they knock the phalli one against another.

Joan Lawson described the tree-worship dance performed both in Australia and up the Amazon River:

> A solemn circling of the tree is followed by an ecstatic raising of the head and hands to the branches, leaves, and fruit. Hands are then gradually run down the trunk and finally the men kneel or lie grovelling at the roots. They hope that by so doing the strength of the tree will enter into them.

An interesting parallel with tribal dances may be found in the break-dancing and "body-popping" craze that swept the United States and Britain in the 1980s. While the dancers clearly were not members of a tribe in any strict sense, they were often members of a distinct group or crew that had its own style and identity. These crews were part of a larger group of young people, again with its own style and customs, that could be differentiated from other groups such as punks or skinheads. The two dance forms were characterized by an energetic spinning action, whereby the dancer propelled himself around on his neck, head, or shoulders and by small, jerky movements of the joints that traveled in a wave through his body. Rival crews often competed with one another in the street, showing off the skill and ingenuity of their moves.

Ethnic dance. In describing many dances, reference is often made to their ethnic, rather than their tribal, origins. An ethnic dance is simply a dance that is characteristic of a particular cultural group. Under this definition even the polka, which is almost always considered a social dance, may be called ethnic, as it began in a culturally distinct region of Europe. Flamenco, which began as an improvised dance among Andalusian gypsies, combines toe and heel clicking with body movements similar to Indian dance. Indian dances may be regarded as a general ethnic type, but there are numerous forms and traditions within the type: some are classical (see above *Indian classical dance*), while others are popular, being danced by nonspecialists for communal festivities and for recreation.

Use of the term ethnic

In this discussion of the art of dance, it is most useful to reserve the designation ethnic for those genres that, while perhaps in a state of transition, are still practiced by a unique cultural group, still retain some of their original communal or ritual functions, and have not yet reached the professionalized state of classical or folk dance.

The many Afro-Caribbean dance forms are usually considered to constitute a distinct ethnic form because they share certain characteristic movements. As in Indian dance, the legs are frequently bent, with the feet stamping out rhythms against the ground. The torso and back are also very mobile, executing sinuous rippling actions or more jerky, rhythmic movements. The body is frequently bent slightly forward, and there is greater use of the hips, which sway and circle in syncopated rhythms. Gestures and facial expressions are used in some narrative dances, but they tend to be much less sophisticated or strictly codified than in Indian dance.

In performance today, most Afro-Caribbean dance companies are made up of both dancers and drummers, the percussion marking out the rhythm and helping to intensify the emotion. Frequently the dancers take turns performing, and there is usually a great deal of informal communication among members of the company on stage. Participation by the audience is often encouraged at the end of the performance, reflecting the communal, rather than theatrical, origins of the form.

FOLK DANCE

When tribal societies in Europe gave way to more structured societies, the old dance forms gradually developed into what are now called folk or peasant dances. For a long time these retained much of their original significance and therefore could have received the modern classification of "ethnic." The Maypole dance, still sometimes performed in England, is a descendant of older tree-worshiping dances, the ribbons that the dancers hold as they dance around the pole symbolizing the tree's branches. The morris dance, also called the moresque because the blackened faces of the dancers resembled the Moors, is a survival of early weapon dances, which were not war dances but an ancient form of religious worship. The types and styles of these different dances were numerous, and, as with tribal dances, many were lost so that information about them often remains sketchy. In the 20th century, efforts to collect national music and dances were made by, among others, Cecil Sharp in England and Béla Bartók in Hungary. These efforts resulted in the revival of certain dances, but they are now danced mainly for recreation, and their original significance has been lost. It is in this conscious revival or preservation of ethnic and national dances for purposes of entertainment that modern folk dance has its origin.

Although different areas and countries have different styles of dance, most of them share common formations and styles of movement. The earliest and simplest formation, the closed circle, is found in all folk dances and derives from the ritual of circling around an object of worship. The dancers grasp one another by the hands, wrists, shoulders, elbows, or waists and face the centre of the circle. In more complex forms dancers move into and out of the circle to perform individual movements or to join into couples; or as the dancers circle, they may weave around one another. In some dances there are two concentric circles, sometimes the inner one of men and the outer one of women.

Another common formation, the chain, involves a long line of dancers, often holding hands or linked by handkerchiefs. The leader may trace a complex, serpentine pattern for the others to follow. Processional dances may travel a long way—even through an entire village. The dancers are mostly in couples, with the procession halting at times for them to dance together.

Many folk dances today are performed in sets, groups of about eight dancers who may perform in all of the above formations but within a restricted space. In other dances, individuals may leave the group and dance on their own.

Folk dance steps are usually quite simple variations on walking, hopping, skipping, and turning. (See above *Basic steps and formations: Folk dance.*) Depending on the particular dance form, these steps may be long, slow, and gliding or short, fast, and springing. The hips are usually held still, though in more vigorous dances the men in particular may crouch, kneel, or even lie on the floor. Some dances involve large jumps and lifts, usually with the man seizing the woman by the waist, lifting her into the air, and possibly turning with her.

There are numerous kinds of holds. For example, two dancers may face each other and hold hands with the arms crossed, link arms, or use a hold similar to that of ballroom dancers. Individual folk dances may also contain distinctive motifs: the dancers may clap their hands, wave handkerchiefs, or clash sticks with one another. Some

M. Howard—ZEFA

Portuguese folk dancers from Algarve performing one of the traditional regional folk dances.

dances contain elements of mime—not only the bows and curtsies of courtship dance but also gestures such as those performed in certain Slavic harvest dances, where the arms are brought up to the chest and opened outward as if presenting something.

Many European folk dances are characterized by a strong emphasis on pattern and formation. The dancers frequently move in an ordered relation to one another, and the steps follow clearly delineated floor patterns on the ground. The circle is the simplest pattern, but the chain, the procession, and the longways dance are also common. (Some of the more complicated patterns are probably due to the influence of the court dances, which systematized and polished the more robust peasant forms.) Although there are numerous exceptions to the rule, the emphasis in many of those dances is on the footwork, rather than on large or vigorous movements of the body.

SOCIAL DANCE

When the early European folk dances—particularly the courtship forms—were incorporated into court dances, they lost many of their boisterous and pantomimic elements. The man no longer thrust forward to embrace the woman or lifted her vigorously into the air, but simply knelt and took her hand. The woman's earlier violent resistance dwindled into a coquettish turn of the head, and energetic strides and runs gave way to simple gliding steps, often forming intricate patterns that were punctuated with small poses, bows, and curtsies.

The social, as opposed to the theatrical, forms that these early court dances inspired gradually became more elaborate and more lively, with small lifts, jumps, and turns being included, as in the galliard and lavolta. Gradually, too, the emphasis began to switch from the tight group formations of many earlier dances to the individual couple. By the end of the 18th century, in dances such as the waltz and, subsequently, the polka, people simply danced in pairs, with group formations reserved for public display. At the same time these dances came to be danced by all classes of people. Steps were simplified, and dancers no longer needed special instruction to perform them.

In the 20th century, ballroom dances became very popular, with new dances, such as the tango and fox-trot, and new variations gradually added to the repertoire. Like the waltz and polka, ballroom dances placed importance on nimble leg- and footwork, with almost no hip movement and the torso only slightly swaying to the rhythm of the dance. The advent of jazz, however, led to other forms of social dance as Western music fell under the influence of the descendants of African slaves in America. During the jazz era of the 1920s, dances like the Charleston and the Black Bottom not only showed the syncopated rhythms, bent knees, crouched torsos, and hip and pelvic movements of African dance but also broke through the dominance of the couple form. People might still dance opposite each other in pairs, but they no longer held each other or danced in unison, and it was perfectly permissible for the dancer to dance singly. As a consequence, dancers no longer followed a set pattern of steps but invented their own within the general style.

Afro-American influence

A dancer without a partner was free to choose the distance and direction in which to travel. Much more vigorous movements of the torso, legs, and arms were possible, as the dancer did not have to worry about getting in his partner's way. The dancer might jump, kick his legs, stretch his arms out to the side or above the head or swing them through the air and might crouch, extend his body, or twist with complete freedom. The lindy and rock and roll brought back contact between the dancers, but it was of a very acrobatic and individualistic kind. The influence of African dance could still be seen in disco and other popular forms, particularly in the characteristic swaying of the hips and the jerky, percussive movements of the torso marking the rhythms of the music.

General works: ANATOLE CHUJOY and P.W. MANCHESTER (comps. and eds.), *The Dance Encyclopedia,* rev. and enl. ed. (1967), a standard reference source with articles about all forms of dance, containing almost 300 photographs; G.B.L. WILSON, *A Dictionary of Ballet,* 3rd ed. (1974), a comprehensive reference source; and CURT SACHS, *World History of the Dance* (1937, reprinted 1965; originally published in German, 1933), a classic study of the dance in all forms, with special focus on origins, although some of Sachs's arguments have been challenged by more recent anthropological studies. LOUIS HORST, *Pre-Classic Dance Forms* (1937, reprinted 1968), a study of early dances; RICHARD KRAUS and SARAH ALBERTI CHAPMAN, *History of the Dance in Art and Education,* 2nd ed. (1981); and WALTER SORELL, *Dance in Its Time* (1981), analyze the subject within a wide cultural and social context. ROGER COPELAND and MARSHALL COHEN (eds.), *What Is Dance?: Readings in Theory and Criticism* (1983), is a collection of essays on the nature of dance and its different styles and forms. Physiological aspects of dance and the mechanics of human movements are discussed in KENNETH LAWS, *The Physics of Dance* (1984).

Choreography: Contemporary works on choreography include FREDERICK RAND ROGERS (ed.), *Dance, a Basic Educational Technique: A Functional Approach to the Use of Rhythmics & Dance as Prime Methods of Body Development & Control, and Transformation of Moral & Social Behavior* (1941, reprinted 1980); PEGGY VAN PRAAGH and PETER BRINSON, *The Choreographic Art: An Outline of Its Principles and Craft* (1963); LA MERI (RUSSELL MERIWETHER HUGHES), *Dance Composition: The Basic Elements* (1965); and DORIS HUMPHREY, *The Art of Making Dances* (1959, reprinted 1981). Reflections on the creative process involved in some of the choreographer's major dance works can be found in MARY WIGMAN, *The Language of Dance* (1966; originally published in German, 1963).

Dance notation: One of the first inventors of dance notation, RAOUL-AUGER FEUILLET, showed the floor pattern of dances in his work *Orchesography* (1706, reprinted 1971; originally published in French, 1700). Other early works on the subject include ARTHUR SAINT-LÉON, *La Sténochorégraphie: Ou, art d'écrire promptement la danse* (1852); and V.I. STEPANOV, *Alphabet of Movements of the Human Body: A Study in Recording the Movements of the Human Body by Means of Musical Signs* (1958, reissued 1969; originally published in French, 1892). Modern works include RUDOLF BENESH and JOAN BENESH, *An Introduction to Benesh Movement-Notation: Dance,* rev. and extended ed. (1969); NOA ESHKOL and ABRAHAM WACHMANN, *Movement Notation* (1958), supplemented with *Movement Notation Survey 1973: Eshkol-Wachmann Movement Notation* (1973); and NOA ESHKOL, MICHAL SHOSHANI, and MOOKY DAGAN, *Movement Notations: A Comparative Study of Labanotation (Kinetography Laban) and Eshkol-Wachmann Movement Notation* (1979). Current studies of dance notation are found in the periodicals *Ballet News* (monthly); and *Dance Notation Journal* (semiannual).

Theatrical aspects of dancing: MARY CLARKE and CLEMENT CRISP, *Making a Ballet* (1974), offers observations on the different relationships between choreographers and dancers, designers, and composers, and their *Design for Ballet* (1978) is a lavishly illustrated survey of costume and set design. MERLE ARMITAGE (ed.), *Martha Graham, the Early Years* (1937, reprinted 1978); and LE ROY LEATHERMAN, *Martha Graham: Portrait of the Lady as an Artist* (1966), explore the nature of this prominent choreographer's work. See also DAVID VAUGHAN, *Frederick Ashton and His Ballets* (1977); and MERCE CUNNINGHAM, *Changes: Notes on Choreography,* edited by FRANCES STARR (1969). For the analysis of technical components of dance as theatre, see ELIZABETH R. HAYES, *Dance Composition and Production for High Schools and Colleges* (1955, reissued 1981); CYRIL W. BEAUMONT and STANISLAS IDZIKOWSKI, *A Manual of the Theory and Practice of Classical Theatrical Dancing (Classical Ballet) (Cecchetti Method),* rev. ed. (1977); and articles on the technical aspects of the art in *Dance Chronicle: Studies in Dance and the Related Arts* (quarterly).

Ballet: Development of the ballet as a theatre art is reflected in the early writings of some dancing masters such as CESARE NEGRI MILANESE, *Nuove inventioni di balli: opera vaghissima* (1604; reissued in 1969 as *Le gratie d'amore*), a richly illustrated treatise. See also CLAUDE FRANÇOIS MÉNESTRIER, *Des Ballets anciens et modernes selon les régles du théâtre* (1682, reprinted 1972), the first printed history of the ballet; DERYCK LYNHAM, *The Chevalier Noverre: Father of Modern Ballet* (1950, reprinted 1972), a biographical history; and THÉOPHILE GAUTIER, *The Romantic Ballet as Seen by Théophile Gautier,* trans. from French by CYRIL W. BEAUMONT (1932, reprinted 1980). LINCOLN KIRSTEIN, *Dance: A Short History of Classic Theatrical Dancing* (1935, reprinted 1970), and *Movement & Metaphor* (1970, reissued as *Four Centuries of Ballet,* 1984), are brilliant analyses of the component parts of ballet and its developments, based on a wide survey of works. An authoritative historical study is JOAN LAWSON, *A History of Ballet and Its Makers* (1964, reprinted 1976). SELMA JEANNE COHEN, *Next Week, Swan Lake: Reflections on Dance and Dances* (1982), is a witty and illuminating discussion of some basic issues in dance criticism. For the analysis of ballet techniques, see JEAN-GEORGES NOVERRE, *Letters on Dancing and Ballets* (1930, reissued 1966; originally published in French, rev. ed. 1803–04), a reformer's statement of the principles of ballet techniques, which are still valid; and CARLO BLASIS, *An Elementary Treatise upon the Theory and Practice of the Art of Dancing* (1944; originally published in French, 1820), a book by an Italian dancer and choreographer who codified the techniques of classic ballet. For the librettos of most famous ballets, see CYRIL W. BEAUMONT, *Complete Book of Ballets: A Guide to the Principal Ballets of the Nineteenth and Twentieth Centuries,* rev. ed. (1949, reprinted 1956), supplemented with his *Ballets of Today* (1954), and *Ballets, Past & Present* (1955); and WALTER TERRY, *Ballet Guide: Background, Listings, Credits, and Descriptions of More Than Five Hundred of the World's Major Ballets* (1982). Contributions of the Russian ballet are discussed by RICHARD BUCKLE, *Diaghilev* (1979, reprinted 1984), and *Nijinsky,* 2nd ed. (1975); and by NATALIA ROSLAVLEVA, *Era of the Russian Ballet* (1966, reprinted 1979).

Modern dance: Various aspects of modern dance and its forms are studied in WALTER TERRY, *The Dance in America,* rev. ed. (1971, reprinted 1981); WALTER SORELL, *The Dance Has Many Faces,* 2nd ed. (1966); and JOHN MARTIN, *Introduction to the Dance* (1939, reissued 1965), especially good on the theory of the early modern dance. Also see SELMA JEANNE COHEN (ed.), *The Modern Dance: Seven Statements of Belief* (1966, reprinted 1973), a collection of essays by important choreographers; SALLY BANES, *Terpsichore in Sneakers: Post-Modern Dance* (1980), a survey of the subject; and JOSEPH H. MAZO, *Prime Movers: The Makers of Modern Dance in America* (1977), which contains useful analyses of many choreographers' works. Current research in choreography is presented in the periodicals *Dancing Times* (monthly); *Dance Research Journal* (semiannual); and *Dance Magazine* (monthly).

Indian classical dance: Analysis of regional dancing is found in KAY AMBROSE, *Classical Dances and Costumes of India,* 2nd ed. (1983), a well-documented description of basic forms and styles; BERYL DE ZOETE, *The Other Mind: A Study of Dance in South India* (1953, reissued 1960); and RINA SINGHA and REGINALD MASSEY, *Indian Dances: Their History and Growth* (1967), a well-illustrated guide.

Folk and social dance: Folk dance is the subject of CECIL J. SHARP and A.P. OPPÉ, *The Dance: An Historical Survey of Dancing in Europe* (1924, reprinted 1972); and JOAN LAWSON, *European Folk Dance* (1953, reprinted 1980). Periodicals include *Arabesque: A Magazine of International Dance* (bimonthly); *American Square Dance* (monthly); and *Square Dancing* (monthly). Social and ballroom dances are analyzed in ARTHUR H. FRANKS, *Social Dance: A Short History* (1963); and PHILIP J.S. RICHARDSON, *The Social Dances of the Nineteenth Century in England* (1960).

(J.R.Ma.)

The History of Western Dance

The peoples of the West—of Europe and of the countries founded through permanent European settlement elsewhere—have a history of dance characterized by great diversity and rapid change. Whereas most dancers of the East repeated highly refined forms of movement that had remained virtually unchanged for centuries or millennia, Western dancers showed a constant readiness, even eagerness, to accept new vehicles for their dancing. From the earliest records, it appears that Western dance has always embraced an enormous variety of communal or ritual dances, of social dances enjoyed by many different levels of society, and of skilled theatrical dances that followed distinct but often overlapping lines of development.

The article FOLK ARTS covers in greater detail the unique nature, techniques, forms, and functions, and the historical developments of each of these kinds of Western dance. In addition, the article DANCE, THE ART OF, covers the aesthetics and the varieties of dance, both Western and non-Western. Aspects of Eastern dance are detailed in the article EAST ASIAN ARTS.

The West cannot always be clearly distinguished from the non-West, especially in such countries as Russia or other regions of the former Soviet Union, where some dances are Asian and others European in origin and character. This article focuses on the dance of Western peoples, noting where appropriate the influence of other cultures.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 625, and the *Index.*

The article is divided into the following sections:

From antiquity through the Renaissance

Before written records were left, a vast span of time elapsed about which scholars can only speculate. Pictorial records in cave paintings in Spain and France showing dancelike formations have led to the conjecture that religious rites and attempts to influence events through sympathetic magic were central motivations of prehistoric dance. Such speculations have been reinforced by observation of dances of primitive peoples in the contemporary world, though the connection between ancient and modern "primitives" is by no means accepted by many scholars. If the dances recorded in early written records represented a continuity from prehistoric dances, there may have been prehistoric work dances, war dances, and erotic couple and group dances as well. One couple dance surviving in the 20th century, the Bavarian-Austrian *Schuhplattler,* is considered by historians to be of Neolithic origin, from before 3000 BC.

DANCE IN THE ANCIENT WORLD

In the civilizations of Egypt, Greece and its neighbouring islands, and Rome, written records supplement the many pictorial remains. Written records alone provide information about ancient Jewish dancing. There are still conjectures about the style, pattern, and purpose of ancient dances, but there is far more concrete evidence.

Ancient Egyptian dance. Formalized ritual and ceremonial dances in which the dancing priest–king represented the person of a god or the servant and regenerator of his people were practiced in Egypt. These dances, culminating in ceremonies representing the death and rebirth of the god Osiris, became more and more complex, and ultimately they could be executed only by specially trained dancers. From Egypt also come the earliest written documentations of the dance. These records speak of a class of professional dancers, originally imported from the interior of Africa, to satisfy the wealthy and powerful during hours of leisure and to perform at religious and funerary celebrations. These dancers were considered highly valuable possessions, especially the pygmy dancers who became famous for their artistry. One of the pharaohs prayed to become a "dance dwarf of god" after his death, and King Neferkare (3rd millennium BC) admonished one of his marshals to rush such a "dance dwarf from the Land of Spirits" to his court.

Professional dancers

There is considerable agreement that the belly dance, now performed by dancers from the Middle East, is of African origin. A report of the 4th century BC from Memphis in Egypt described in detail the performance of an apparently rumba-like couple dance with an unquestionably erotic character. The Egyptians also knew acrobatic exhibition dances akin to the present-day adagio dances. They definitely were aware of the sensual allure of the sparsely clad body in graceful movement. A tomb painting from Shaykh ʿAbd al-Qurnah, now in the British Museum, shows dancers dressed with only rings and belts, apparently designed to heighten the appeal of their nudity. These figures probably were intended to entertain the dead as they had been entertained in life.

Egyptian dancing, detail from a tomb painting from Shaykh 'Abd al-Qurnah, Egypt, *c.* 1400 BC. In the British Museum.

Egypt, then, presented a dancing scene that was already varied and sophisticated. In addition to their own danced temple rituals and the pygmy dancers imported from the headwaters of the Nile, there were Hindu dancing girls from conquered countries to the east. This new dance had none of the long masculine strides or the stiff, angular postures seen in so many Egyptian stone reliefs. Lines of movement undulated softly, nowhere bending sharply or breaking. These Asiatic girls brought a true feminine style to Egyptian dance.

Dance in classical Greece. Many Egyptian influences can be found in the Greek dance. Some came by way of Crete, others through the Greek philosophers who went to Egypt to study. The philosopher Plato (*c.* 428–348/47 BC) was among them, and he became an influential dance theoretician. He distinguished dances that enhance the beauty of the body from awkward movements that imitate the convulsions of ugliness. The Apis cult dances of Egypt had their equivalent in the Cretan bull dance of about 1400 BC. It inspired the labyrinthine dances that, according to legends, Theseus brought to Athens on his return with the liberated youths and maidens.

Another dance form that originated in Crete and flourished in Greece was the *pyrrhichē,* a weapon dance. Practiced in Sparta as part of military training, it was a basis for the claim of the philosopher Socrates that the best dancer is also the best warrior. Other choral dances that came to Athens from Crete include two dedicated to Apollo and one in which naked boys simulated wrestling matches. Female characteristics were stressed in a stately and devout round dance in honour of the gods, performed by choruses of virgins.

Numerous vase paintings and sculptural reliefs offer proof of an ecstatic dance connected with the cult of Dionysus. It was celebrated with a "sacred madness" at the time of the autumnal grape harvest. In his drama *Bacchae,* Euripides (*c.* 480–406 BC) described the frenzy of Greek women, called bacchantes or maenads. In their dance for generation and regeneration, they frantically stamped the ground and whirled about in rhythmic convulsions. Such dances were manifestations of demoniacal possession characteristic of many primitive dances. Dionysian dances

The Dionysian cult brought about Greek drama. After the women danced, the men followed in the disguise of lecherous satyrs. Gradually the priest, singing of the life, death, and return of Dionysus while his acolytes represented his words in dance and mime, became an actor. The scope of the dance slowly widened to incorporate subjects and heroes taken from the Homeric legends. A second actor and a chorus were added. In the lyric interludes between plays, dancers re-created the dramatic themes in movements adopted from the earlier ritual and bacchic dances. In the comedies, they danced the very popular kordax, a mask dance of uninhibited lasciviousness. In the tragedies, the chorus performed the *emmeleia,* a dignified dance with flute accompaniment.

These dances and plays were executed by skilled amateurs. At the end of the 5th century BC, however, there came into being a special class of show dancers, acrobats, and jugglers, the female members of which were evidently hetaerae, members of a class of courtesans. No doubt influenced by Egyptian examples, they entertained guests at lavish banquets. The historian Xenophon (*c.* 430–*c.* 355 BC) in his *Symposium* tells of the praise Socrates lavished on a female dancer and a dancing boy at one such occasion, finally himself emulating their beautiful movements. Elsewhere, Xenophon describes a dance representing the union of the legendary heroine Ariadne with Dionysus, an early example of narrative dance.

Ancient Roman dance. There was a striking difference between the Etruscan and the Roman peoples in their approach to the dance. Little is known about the Etruscans, who populated the area north of Rome up to Florence and flourished between the 7th and 5th century BC. But it is apparent from their lavish tomb painting that dance played an important part in their enjoyment of life. Women were enthusiastic participants in Etruscan dancing; funerary chain dances were performed by groups of women, and lively, energetic couple dances are portrayed in Etruscan frescoes. They were performed without masks in public places and showed a distinct courting character.

Roman antagonism to dance seems to reflect a sober rationalism and realism. Nonetheless, Rome did not entirely evade the temptations of dance. Before about 200 BC, dances were evidently in the form of choral processions only. There were agricultural processions headed by priests, and weapon dances of the Salii, a congregation of the priests of Mars who walked around in a circle while rhythmically beating their shields. Dancing was an important part of Roman festivals—the celebrations of Lupercalia and Saturnalia featured wild group dances that were precursors of the later European carnival. Antagonism of the Romans

Later, Greek and Etruscan influences began to spread, though people who danced were considered suspicious, effeminate, and even dangerous by the Roman nobility. One public official did not believe his eyes when he watched dozens of the daughters and sons of well-respected Roman patricians and citizens enjoying themselves in a dancing school. About 150 BC all dancing schools were ordered closed, but the trend could not be stopped. And though dance may have been alien to the Roman's inner nature, dancers and dancing teachers were increasingly brought from abroad in the following years. The statesman and scholar Cicero (106–43 BC) summed up the general opinion of the Romans when he stated that no man danced unless he was insane.

A form of dance that enjoyed great popularity with the Romans under the emperor Augustus (63 BC–AD 14) was the wordless, spectacular pantomime that rendered dramatic stories by means of stylized gestures. The performers, known as *pantomimi,* were at first considered more or less as interpreters of a foreign language, since they

came from Greece. They refined their art until the two dancer-mimes Bathyllus and Pylades became the star performers of Augustan Rome. The stylized performance of the dancer, who wore a mask appropriate to the theme of his dance, was accompanied by musicians playing flutes, horns, and percussion instruments and a chorus that sang about the action between dance episodes.

Jewish dance. When dance is mentioned in the Old Testament it is distinguished by its joyousness. Words such as leaping and whirling describe the energy and vitality of ancient Hebrew dances. As in other early societies, dancing is most often connected with ritualistic activity. Ring dances may have been performed in the worship of the golden calf; the prohibition against making graven images that resulted from this worship explains the lack of evidence of Jewish dances in the visual arts.

Hebrew dances were performed by both men and women, though usually the sexes were separated. Victory dances were performed by groups of women; men participated in ecstatic whirling dances designed to evoke prophecy. Festival dances were performed by both groups—one of the most important was the water-drawing festival on the first night of Sukkoth, which was celebrated by a torchlit procession dance that lasted through the night.

Weddings provided another important occasion for ritual dancing. Dancing with the bride was considered an act of devotion, and the officiating rabbi always complied with pleasure. During the Diaspora of the early Christian Era many of the ritual dances disappeared, but the bridal dance continued as a tradition. In the Middle Ages a wedding dance called the *mitzvah* was performed; because of the segregation of the sexes men danced with the bridegroom and women with the bride. Later, men could dance with the bride either by wrapping their hands in a cloth or by holding a cloth between them to signify their separation.

CHRISTIANITY AND THE MIDDLE AGES

Dancing was traditional also among the tribes of barbarians to the north, as attested by the writings of the Christian missionaries. Wherever they went, they found the same fertility-rite dances—if in different guise, the same charm dances to induce good and ward off evil, the same warrior and weapon dances to bolster fighting morale, and the same uncontrolled expressions of the joy of life, which the missionaries attributed to the devil.

Erotic dancing was not the exclusive property of heathen societies. In Byzantium, the Christian emperor Justinian I (483–565) married the notorious Theodora, a dancer who had appeared in the nude in theatrical performances. About 500, St. Caesarius of Arles reported a sacrificial banquet ending in some demoniacal dancing rites performed to the accompaniment of lewd songs. The Anglo-Saxons had little girls performing dances at Easter in which a phallus was carried in front of them.

Ecclesiastical attitudes and practices. The attitude of the Christian Church toward dance was not unanimous. On the one side there was the ascetic rejection of all manifestations of lust and ecstasy, and dance was seen as one of the strongest persuasions to sexual permissiveness. On the other side, some early Church Fathers tried to find functions for pagan dances in Christian worship. St. Basil of Caesarea in 350 called dancing the most noble activity of the angels, a theory later endorsed by the Italian poet Dante. St. Augustine (354–430) was strictly against dancing, but, despite his great influence in the medieval church, dancing in churches continued for centuries.

Ambivalence of the church

Charlemagne, the Holy Roman emperor at the beginning of the 9th century, officially prohibited all kinds of

dancing, but the ban was not observed. The Teutonic peoples were accustomed to dancing as part of their religious rites. On Christian feast days, which coincided with their ancient rites of expelling the winter, of celebrating the arrival of spring, and of rejoicing that the days grew longer again, they revived their old ritual dances, though these were camouflaged with new names and executed to different purpose. In this manner previously sacred dances became more and more secularized. After such secularization, two lines of development were open: the social dance or the assimilation of dance into theatrical spectacle by the joculators, travelling comedians who combined the arts of dancer, juggler, acrobat, singer, actor, mime, and musician in one person.

Dance ecstasies. There were two kinds of dance peculiar to the Middle Ages, the dance of death, or danse macabre, and the dancing mania known as St. Vitus' dance. Both originally were ecstatic mass dances, dating from the 11th and 12th centuries. People congregated at churchyards to sing and dance while the representatives of the church tried in vain to stop them. In the 14th century another form of the dance of death emerged in Germany, the *Totentanz,* a danced drama with the character of Death seizing people one after the other without distinctions of class or privilege. The German painter Hans Holbein the Younger (1497/98–1543) made a famous series of engravings of this dance.

The dance of death

The St. Vitus' dance became a real public menace, seizing hundreds of people, spreading from city to city, mainly in the Low Countries, in Germany, and in Italy during the 14th and 15th centuries. It was a kind of mass hysteria, a wild leaping dance in which the people screamed and foamed with fury, with the appearance of persons possessed. In these convulsive, frantic, and jerky dances, religious, medical, and social influences probably interacted in response to such things as the epilepsy-like seizures of persons suffering from the Black Death. Italy was afflicted with tarantism, an epidemic presumably caused by the bite of venomous spiders. Its effects had to be counteracted by distributing the poison over the whole body and "sweating it out," which was accomplished by dancing to a special kind of music, the tarantella.

Dance and social class. In western Europe by the 12th century, society had developed into three classes, the nobility, the peasantry, and the clergy. This separation contributed to the development of the social dance. The knights created their own worldly and spiritual ideals, exemplified in tournaments and courtly entertainments that were praised in song and poetry by the troubadours and minnesingers. The couple dances of the knights expressed the polished and aristocratic notions of courtly love. The round dances of the peasants were executed by circles or lines of people, often singing and holding each other by their hands. The rustic choral round had strong pantomimic leanings and unpolished expressions of joy and passion. And while the choral rounds almost always were executed to the singing of the participants, the court dances of the knights generally were accompanied by instrumental playing, especially of fiddles, and when there was singing, it emerged from the spectators rather than the performers.

Courtly couples and rustic rounds

From the late Middle Ages, graphic artists frequently recorded what dancing looked like in all its different manifestations. How dancing adapted to the idealism of knightly love is shown in manuscript illuminations and tapestries. Paintings of the Flemish painter Pieter Bruegel the Elder (*c.* 1525/30–69) leave no doubt that the peasants enjoyed celebrating with dances of uninhibited stamping and cavorting.

THE RENAISSANCE WORLD AND THE ART DANCE

France had set the fashion in court dance during the late Middle Ages; with the Renaissance, however, Italy became the centre of the new developments in dance. The Renaissance brought greater mixing of social classes, new fortunes and personal wealth, and greater indulgence in worldly pleasures and in the appreciation of the human body. The period emerged as one of the most dance-conscious ages in history.

Court dances and spectacles. Celebrations and festivities proliferated. The itinerant jugglers of the Middle Ages became highly respected and much sought after as dancing masters. They quickly assumed the function of instructing the nobility not only in the steps but also on posture, bearing, and etiquette. They became responsible for the planning and realization of the spectacular festivities. The social prestige of this newly developing profession grew constantly.

Some of these dancing masters were highly learned men, and their treatises leave no doubt about their scholarly ambitions. Many of them were Jewish, descended from the Klesmorim, a group of medieval Jewish entertainers. The first dancing master known by name was Domenico da Piacenza, who in 1416 published the first European dance manual, *De arte saltandi et choreas ducendi* ("On the Art of Dancing and Directing Choruses"). His disciple, Antonio Cornazano, a nobleman by birth, became an immensely respected minister, educator of princes, court

poet, and dancing master to the Sforza family of Milan, where about 1460 he published his *Libro dell'arte del danzare* ("Book of the Art of the Dance"). Such books record little about the actual steps and the melodies to which they were performed, but they are eloquent in the description of the *balli*—works that were invented by the dancing masters themselves. Adapting steps from the various social dances, they used them in a kind of dance pantomime.

In France, numerous forms developed from the branle, a round dance of peasant origin that became fashionable in the courts. One of the most frequently mentioned of all the dances of the 15th century was the *morisca,* or *moresque,* a romanticized version of dances from Moorish Spain. These were first mentioned in 1446 by a Bohemian traveller who visited Burgos, Spain. Later, in Portugal, he encountered similar forms. Sometimes religious motifs of the legendary fight between Charlemagne and the Turkic invader Timur entered the *morisca,* but usually it was performed as a double-file choral dance. It had nothing to do, as was long believed, with the English masked Morris dance, now considered to be a survival from a primitive religious cult.

From such choral dances the ballet emerged. At the court entertainments throughout Savoy and northern Italy, sumptuous spectacles with mythological, symbolical, or allegorical content became increasingly popular. At these early stages, however, pantomime and dance are not easily distinguished. Famous examples of these spectacles are the presentation of the story of Jason and the Golden Fleece at the marriage of Philip the Good of Burgundy in 1430, and the dinner ballet on the same, though widely enlarged, subject staged for the wedding of the Duke of Milan in 1489.

Tudor England of the early 16th century had similar pageants, with the participants disguising "after the manner of Italie." Like the Italian *balli,* the English masque offered an almost unlimited choice of performing variations, from a simple dance in masks to the most elaborate spectacle interspersed with songs, speeches, and pantomimes. As for the actual dances, Robert Copland's *Maner of Dauncynge of Bace Daunces after the Use of Fraunce,* published in 1521 as an appendix to a French grammar, leaves no doubt that the English upper class of that period was thoroughly familiar with continental dance. But whereas the nobility preferred dances of slow, measured, and dignified stature, stylishly performed and modelled upon the standards of the French court, the peasants continued their boisterous dancing, in England as elsewhere, very much as they had for centuries.

In England in the late 16th century, Queen Elizabeth I gave dancing a further boost. She was a skilled practitioner of the galliard and the volta, with its tight embraces by high-leaping couples. She enjoyed watching the English country dances—the chain, ring, and round dances of ancient origin and constantly new invention. These dances apparently provided a continuous infusion of new vitality into court dances. The nobles vied with one another in the execution of the jig, a sprightly and swift dance of "the folk" accompanied by songs. Dancing schools flourished everywhere in London, giving public displays and contributing considerably to the reputation of "the dancing English." Another extremely important contribution to dance was provided by Spain, which in the late 16th and early 17th centuries enjoyed a cultural renaissance. It was the "golden age" of Cervantes in literature, of Lope de Vega and Pedro Calderón de la Barca in the theatre, of El Greco and Diego Velásquez in painting. With the growth of Spain's empire in the Americas, dances of Afro-American origin found their way back to Europe. The sarabande and the chaconne were brought from Central America before 1600. Both were considered outspokenly obscene in their suggestions of sexual encounters. They became extremely popular in the harbours of Andalusia, where they were polished and their pantomimic literalness somewhat moderated. From there they crossed the Pyrenees and were integrated into the canon of the French court dance.

Spread of Spanish dance

Other dances from abroad played major roles in the shaping of Spain's national dances. The *canarie* of African origin certainly sired the Aragonese jota, while the sarabande brought forth the seguidilla. The Afro-Cuban *chica* lived on in the fandango, and the flamenco dances of the Andalusian Gypsies retained their Moorish heritage into the 20th century. It can be presumed that this exchange of dances was not a one-way traffic, that the European conquerors and colonists similarly influenced the dancing habits of the people in other lands.

The birth of ballet. Meanwhile, dance became the subject of serious studies in France. A group of writers calling themselves La Pléiade aimed for a revival of the theatre of the ancient Greeks with its music, song, and dance. In Catherine de Médicis (1519–89), the Florentine wife of Henry II, the Italian dancing masters found an influential sponsor in Paris. She called to Paris the Italian musician and dancing master Baltazarini di Belgioioso, who changed his name to Balthazar de Beaujoyeulx (early 16th century to 1587). There had been previous fetes in both France and Italy that offered masquerades, pantomimes, and dances with allegorical and symbolical subjects, but none of them compared to the splendours of the *Ballet comique de la reine* that Beaujoyeulx staged in 1581 for Catherine.

Ballet comique de la reine

This "ballet" told the story of the legendary sorceress Circe and her evil deeds. Spoken texts alternated with dances amid magnificently decorative settings. The performers, recruited from the nobility, moved on the floor more like animated costumes than individual dancers. They came together in strikingly designed groups, and they set up geometrical floor patterns that had highly symbolic meanings. (To audiences of the period, for example, three concentric circles represented Perfect Truth, and two equilateral triangles within a circle stood for Supreme Power.) The ballet, which ended in an act of homage to the royal majesties present, had a distinct political moral. Circe had to render her might to the absolutist power of the king of France as the supreme symbol of a peaceful and harmonious world.

The *Ballet comique* launched the species known as *ballet de cour,* in which the monarchs themselves participated. The idealized dances represented the supreme order that France itself, suffering from internal wars, lacked so badly. The steps were those of the social dances of the times, but scholars became aware of how these native materials might be used to propagate the Greek revival. They thoroughly analyzed and systematized the dances, and in 1588 the priest Jehan Tabourot, writing under the pen name Thoinot Arbeau, published his *Orchésographie,* which he subtitled "a treatise in dialogue form by which everyone can easily learn and practice the honest exercise of the dance." This was the first book containing reliable descriptions of how, and to what kind of music, the *basse danse,* pavane, galliard, volta, courante, allemande, gavotte, *canarie, bouffon, moresque,* and 23 different variations of the branle were performed.

During the 17th, 18th, and 19th centuries

Under kings Louis XIV and Louis XV, France led western Europe into the age of the Rococo in the arts. The Rococo began as a movement toward simplicity and naturalness, a reaction against the stilted mannerisms and preciousness to which the earlier Baroque art was considered to have degenerated. It was a great age of and for dancing, with the minuet the symbol of its emphasis on civilized movement. This formal dance, the perfect execution of which was almost a science in itself, reflected the Rococo idea of naturalness. The statement that "the dance has now come to the highest point of its perfection" by the composer Jean-Philippe Rameau (1683–1764) suggested how conscious the French were of the great strides dance had made. That this was particularly the case in France was confirmed by the English poet and essayist Soame Jenyns (1704–87) in his lines "None will sure presume to rival France, / Whether she forms or executes the dance." None, however, excelled the estimation of his profession by the dancing master in Molière's *Le Bourgeois Gentilhomme* (1670):

> There is nothing so necessary to human beings as the dance . . . Without the dance, a man would not be able to do anything. . . . All the misfortunes of man, all the baleful reverses with which histories are filled, the blunders of politicians and the failures of great leaders, all of this is the result of not knowing how to dance.

THE MATURING OF BALLET

Dance was finally deemed ready for an academy of its own. In 1661, 13 dancing masters who had been members of a professional guild of medieval origin, together with some musicians, composers, and the makers of instruments, were granted a charter by Louis XIV for the Académie Royale de Danse.

Technical codifications and dance scholarship. The academicians were charged with setting up objective standards for perfecting of their arts, with unifying the rules of dance training, and with issuing licenses to dancing instructors. Though the nobility continued for some time to participate in the *ballets de cour,* and Louis himself danced in them until 1669, the dance became more and more the province of highly trained specialists.

After 1700 ballet and social dance took separate paths. But while the ballet continued to absorb new ideas from the folk and social dance, its practitioners and theoreticians looked down on those more common forms. A profusion of books on dance began to appear—treatises, instructions, and analyses as well as the first attempts to record dances by means of written notation. The first history of dance was Claude-François Menestrier's *Des ballets anciens et modernes* ("On Dances Ancient and Modern"; 1682). The second major work of European dance literature, after Arbeau's *Orchésographie,* was Raoul Feuillet's *Chorégraphie, ou l'art de décrire la danse* ("Choreography, or the Art of Describing the Dance"; 1700). It became the standard grammar for the dances practiced at the turn of the century, describing them in minute detail and notating them by a system devised by Feuillet. This indicated the position of the feet and directions, combinations, and floor patterns of the steps and leaps. The notations system was unable, however, to register the movements of the upper parts of the body. Feuillet provided as well a complete definition of the principles of the dance first described by the Académie in the 1660s. These included the *en dehors* (*i.e.,* the turnout of the body and its limbs), the five classical positions of the feet, the port de bras (*i.e.,* the positions and movements of the arms), and the leaps to the *grande élévation,* the aerial movements of the dance.

Early works about ballet

In 1706 Feuillet's influential book was translated into English by John Weaver (1673–1760), a dancer, choreographer, and teacher who worked mainly at the Drury Lane Theatre, London. In 1717 he produced one of the first serious ballets without words, *The Loves of Mars and Venus.* Weaver was the first dance teacher to insist that dance instructors should have a thorough knowledge of human anatomy. In 1721 he published his *Anatomical and Mechanical Lectures upon Dancing,* which became a standard work of international importance. Germany also was represented in the field of dance scholarship, most notably by Leipzig Gottfried Tauber in *Der rechtschaffene Tanzlehrer* ("The Correctly Working Dance Teacher"; 1717). These books strongly emphasized the contributions of dance to general education and manners. In this period dance was considered the basis of all education, and well-to-do parents went to great pains to have their children properly instructed.

Varieties of the ballet. As the technical demands of performance became greater and the amateurs gave way to the professionals, performance of the ballet moved from the dance floor onto the stage. There it gradually shed its declamations and its songs and concentrated on telling a story through the gestures of dance and mime alone. But this purifying process took time. For decades different forms of mixed-media spectacles were seen, from the *comédies-ballets* of Molière (1622–73) and the composer Jean-Baptiste Lully (1632–87) to the *opéras-ballets* of André Campra (1660–1744) and Rameau, which were successions of songs and dances on a common theme. The first ballet to be performed without the diversions of speech or song was *Le Triomphe de l'amour* (*The Triumph of Love;* 1681), choreographed by Charles-Louis Beauchamp (1636–*c.* 1719) to Lully's music. Originally a *ballet de cour,* it was revived for the stage with a professional cast. Its star, Mlle Lafontaine, became ballet's first *première danseuse* exactly 100 years after the *Ballet comique* had been produced.

An even more dramatic form known as *ballet d'action* came into being in 1708, when two professional dancers presented an entire scene from the tragedy *Horace* by Pierre Corneille (1606–84) in dance and mime. Weaver's silent ballets, whose expressive dance much impressed English audiences, also encouraged Marie Sallé, a highly ambitious dramatic dancer. Despairing of the *opéras-ballets* of Paris, she went to London, where she performed in pantomimes and produced a miniature dance-drama of her own, *Pygmalion* (1734). In it she appeared in a flimsy muslin dress and loose, flowing hair rather than the heavy costumes and elaborate wigs usually worn by ballerinas. Thus lightened, the dancer was able to move with much greater freedom.

Early virtuosos of the dance. The era of the great dancer was at hand. Marie Sallé (1707–56) was the greatest dancer-mime and an important innovator of her day. Her popularity was rivalled by the Brussels-born Marie Camargo (1710–70), who excelled Sallé in lightness and sparkle. She used the entrechat, a series of rapid crossings of the legs that previously had been used only by male dancers. To show off properly her entrechats and other lithe footwork, she shortened her skirt by several inches, thereby contributing to costume reform. Both ballerinas were depicted by Nicolas Lancret (1690–1743), a painter

Sallé, Camargo, and Campanini

Giraudon—Art Resource/EB Inc

"La Camargo Dancing," oil painting of Marie Camargo by Nicolas Lancret, 1730. In the Musée des Beaux-Arts, Nantes, France.

known for his festive scenes, and both were praised by the writer and philosopher Voltaire (1694–1778), who carefully compared their respective virtues. Both, however, were surpassed by the Italian dancer Barberina Campanini (1721–99), whose fame is less adequately recorded in dance history. By 1739, she had taken Paris by storm, demonstrating jumps and turns executed with a speed and brilliance hitherto unknown. She offered ample proof that the Italian school of dance teaching had by no means died out with the earlier exodus of so many of its best practitioners to the French courts. Despite the great public acclaim that these ballerinas attracted, they were overshadowed by Louis Dupré (1697–1744), known as "The Great Dupré" and "the god of the dance." In grace, majesty, and allure, he was unsurpassed, giving the male dancer a prominence he held for a century. Dupré was also the first of a direct line of great dance teachers that was unbroken in the late 20th century.

THE REIGN OF THE MINUET

In the realm of the social dance, the years between 1650 and 1750 were called "the age of the minuet" by the dance and music historian Curt Sachs.

The French dance suite. At the great balls of the French court at Versailles, the minuet was the high point of the festivities, which culminated in a suite of dances. The opening branle, led by the king and his escort, was a measured circling around, one couple after another. Next came the courante, which had been toned down from its earlier rather capricious figurations. Over the years it assumed a continuously greater dignity until it was danced with such gravity and sobriety that it was termed the "doctor dance." It went quickly out of fashion, however, after 1700. Following the courante in the succession was the gavotte, which opened in the form of a round dance. A couple separated to each perform a short solo, then returned to the original circle. Sometimes the suite was extended through an allemande (French: "German"), an old dance form that was introduced into France from the heavily German-speaking province of Alsace in the 1680s. This dance, with its turning couples, the lady on the arm of the gentleman, was a relative of the German ländler and a precursor of the waltz.

The dance suite

Form of the minuet. But the unrivalled king of the social dances was the minuet, named from the *pas menu* ("small step"), a term used at least as early as the 15th century. The earliest surviving specimen was composed by Lully in 1663. Mozart composed a series of 12 minuets as late as 1789. It originated as a folk dance in Poitou, but as a court dance it took its form from the courante. Though today it looks mannered, even artificial, in its time it was looked upon as the most beautiful and harmonious of dances, and to execute it perfectly required prolonged and careful study:

> The *minuet* was performed in open couples; spectators and partners were saluted with ceremonial bows. With dainty little steps and glides, to the right and to the left, forward and backward, in quarter turns, approaching and retreating hand in hand, searching and evading, now side by side, now facing, now gliding past one another, the ancient dance play of courtship appears here in a last and almost unrecognizable stylization and refinement. (Curt Sachs, *World History of the Dance,* trans. Bessie Schönberg, W.W. Norton & Co., Inc., 1937.)

In spite of the great popularity of the minuet before the French Revolution, it was the object of much barbed commentary in the late 18th century. Voltaire compared the metaphysical philosophers of his time with the dancers of the minuet, who, in their elegant attire, bow and mince daintily across the room showing off their charms, move without progressing a single step, and end up at the very spot from which they began.

ENGLISH SOCIAL DANCE

England thoroughly democratized the dance. Though the English Puritanism of the 17th century stigmatized dance as one of man's most sinful occupations, even Oliver Cromwell, lord protector of England under the Puritan rule in the 1650s, could not prevent the appearance of *The English Dancing Master* (issued 1650; dated 1651), by the bookseller and publisher John Playford (1623–*c.* 1686). This was a collection of English traditional dances and tunes. It had 18 editions in 80 years, each one adding to the repertoire. Its 900 choral dances of rustic origin, which formerly had been danced in the open air but were now usually performed indoors, included an enormous variety of forms and patterns. It was written in straightforward, matter-of-fact language, with no discrimination of dances by social class. Its instructions could be understood and its dances performed by anyone. People could enjoy dancing as a playful, sportive activity rather than as an exercise of courtly etiquette.

These "country dances" could as well be city dances, as is suggested by such names as "Mayden Lane" and "Hide Park" from London locales. Others were named for persons—"Parson's Farewell" and "My Lady Foster's Delight"—and that there were foreign influences can be surmised from "The Spanish Jeepsie" and "A la Mode de France." At the same time, native jigs and hornpipes continued to flourish. The English were particularly fond of the Morris dance. This dance may have received its name from the blackened faces of some of its participants, suggestive of the African Moors, but its origins were in the ancient ritual dances. It was a vigorous male dance, in the form of a dance procession through town streets. Its participants, in the disguises of such popular characters as the fool or the Queen of May, wore jingling bells around their ankles and sometimes galloped about on hobby horses. Other dancers wore antlers, tails, and similar animal masking.

The Morris dance

About 1700 the English country dances began to appear on the Continent, where they were somewhat formalized and sometimes substantially altered. In France they were named contredanses. The longways, dances with double lines of dancers facing one another, became *contredanses anglaises;* the rounds became the *contredanses françaises,* which were also known as cotillions and quadrilles. These figure dances, which quickly spread to Spain, Germany, Poland, and other countries, were the dances of the rising middle class. By no means revolutionary in their content, they were nonetheless a distinct declaration of rationality and common sense in dance, a counterbalance to the artificialities and mannerisms of the aristocratic court dances. The orthodox dance teachers might bemoan the decline from the standards that were epitomized in the minuet,

17th- and 18th-century dance.

but the townspeople and peasants, unconcerned with such niceties, continued in their uncomplicated knowledge that dancing could be fun.

DANCE IN COLONIAL AMERICA

Attitudes. The English colonists in America had mixed opinions about dance. There was the complete disapproval of those who saw only its inherent licentiousness, but from others came at least a tacit toleration of the obviously irrepressible urge to dance. The South, more heavily populated by colonists with aristocratic backgrounds, was generally more inclined to dance than the North, where religious fervour had motivated much of the migration from England. But what was allowed and even encouraged in Connecticut was strictly forbidden in Massachusetts. The general consensus was apparently that dancing in itself was not bad, but that no punishment could be severe enough for what was regarded as lascivious dancing. The Quakers, who had settled mainly in Pennsylvania, were very much against dancing, and in 1706 they complained bitterly about a dancing and fencing school being tolerated in Philadelphia. They feared that the school's teachings would tend to corrupt their children.

External and internal influences. Nonetheless, Playford's *The English Dancing Master* was by no means unknown in America. There were also dancing masters and dancing mistresses to instruct in and lead the dances that had been brought from the Old World. There were society balls in the cities along the coast, and on the inland frontiers the settlers of the widely scattered farmsteads often came together for exuberant feasting and social dancing. Here dancing was considered a socializing virtue expressed in this anonymous observation:

> I really know among us of no custom which is so useful and tends so much to establish the union and the little society which subsists among us. Poor as we are, if we have not the gorgeous balls, the harmonious concerts, the shrill horn of Europe, yet we delight our hearts as well with the simple negro fiddle.

Slave dances

What the colonists saw of American Indian dancing they found very strange and primitive, and there was virtually no exchange of dancing customs between the groups. The situation differed, however, with regard to the black slaves, who in the 17th century had brought their own songs and dances from their native lands in Africa.

During religious holidays in New Amsterdam, blacks danced in the streets to the musical accompaniment of three-stringed fiddles and drums constructed from eel pots and covered with sheep-skins. Dutch families joined in the festivities. When New Amsterdam became New York, however, the English discouraged dancing between whites and blacks; blacks went on to develop the characteristic dance style that would so deeply affect social dancing in the 19th and 20th centuries.

Early in the 18th century, rather rough theatrical entertainments, acts of acrobatic skill or pantomimes in which dances played an increasing role, began to spread through the American colonies. These often amateurish showings got a mighty boost when the first professional companies came from Europe, about the middle of the century, to perform plays and harlequinades with incidental dances.

THE RISE OF THE WALTZ

The age of the minuet was followed by that of the waltz. As the French Revolution approached, the minuet, a form that exuded the essence of earlier decades, died a natural death. The English country dances, expressing the self-satisfaction of the bourgeoisie, fared little better.

The Romantic movement in dance. The young people, whose preferences led the way in creating new forms, had lived through the revolutionary events of the 1780s and '90s. They now looked to dance as a way to unleash deeper emotion, to satisfy the needs of body and soul, and to mobilize more vital and dynamic expression than that permitted by the sober and decorous rules of the dancing masters. The overflow of feeling and the striving for horizons broader than those understood by the traditional canons of French Rationalism were among the factors that generated the Romantic movement in the arts of Europe. This new direction was clearly expressed in the waltz, a dance filled with the Dionysian spirit.

Dionysius revived

Like much of the spirit of the Romantic movement, the waltz was of German origin. It paralleled the Sturm und Drang movement in German literature, which featured the new forms of prose and poetry by Johann von Goethe and Friedrich Schiller. One of the most glowing advocates of the waltz was Goethe, who time and again praised it, nowhere more than in his novel *Die Leiden des Jungen Werthers* (1774; *The Sorrows of Werter,* 1779): "Never have I moved so lightly. I was no longer a human being. To hold the most adorable creature in one's arms and fly around with her like the wind, so that everthing around us fades away." Even the aristocrats who formed the Congress of Vienna in 1815, which sought to restore law and order to Europe following the upheavals brought on by Napoleon, delighted in performing this earliest of all nonaristocratic ballroom dances.

Spread of the waltz. The waltz started as a turning dance of couples. It was especially popular in south Germany and Austria, where it was known under such different names as *Dreher,* ländler, and *Deutscher.* More than any other dance it appeared to represent some of the abstract values of the new era, the ideals of freedom, character, passion, and expressiveness. This may explain somewhat its eruption into the limelight of international popularity. This popularity was scaled in 1787 when it was brought to operatic stage. Vienna became the city of the waltz, for there it surpassed everything in wild fury. It swept over national frontiers, and in 1804 the French were reported to be passionately in love with this light, gliding dance. "A waltz, another waltz" was the common cry from the ballroom floor, for the French could not get enough of the dance.

Some guardians of the public morality disapproved of the "mad whirling" of the waltz and it did not arrive in England until 1812. At the Prussian court in Berlin it was forbidden until 1818, though Queen Luise had danced it while still a princess in 1794. The guardians could do no more than delay its total victory, and it conquered the world without sanction of courts, of dancing masters, or of other powers. After many centuries of leadership, France no longer set the fashions. In 1819 Carl Maria von Weber's *Invitation to the Dance* represented the declaration of love of classical music to the waltz. Shortly thereafter began the age of the Viennese waltz kings, most notably expressed by the Strauss family.

Offspring and rivals. The waltz sired a great variety of offspring throughout Europe. Germany developed such variations of the waltz as the schottisch, with turns like those of the waltz. France had its airy *balance valse,* and the Americans later on had their Boston waltz, a slower,

gliding variant. About 1840 a serious rival to the waltz emerged in the polka, a Bohemian dance that took its name from the Czech word *půlka*, "half step." It was full of fiery vigour. Another Bohemian folk dance finding favour in the dance halls was the *rejdovák* or redowa, while Poland's mazurka and krakowiak enjoyed great popularity. No ball could be concluded without a galop, in which couples galloped through the hall with accelerated polka steps, an exhausting exercise that required considerable reserves of stamina.

FOUNDATIONS OF MODERN BALLET

The ideals of naturalness, character, soul, passion, and expressiveness came to govern the ballet.

Noverre and his contemporaries. The French dancer-choreographer-teacher Jean-Georges Noverre (1727–1810) was the first major reformer of ballet. He defined his artistic positions in *Lettres sur la danse et sur les ballets* (*Letters on Dancing and Ballets*), published in 1760 and continuously reprinted ever since. He worked in Paris, London, Stuttgart, and Vienna, and his influence spread as far as St. Petersburg. He preached the dignity of the ballet and tried to purge it of its excessive artificialities and conventions. He choreographed subjects of mythology and history in highly dramatic narrative forms. He collaborated with some of the major composers of the period, including Mozart, on his ballets.

The influence of Noverre

Noverre was not alone, and the others around him were full of the same zest to give a new meaning to ballet. In Vienna he had a feud with the Italian choreographer Gasparo Angiolini (1731–1803) over Noverre's reforms of the *ballet d'action*. Angiolini claimed these for his teacher, the Austrian choreographer Franz Hilverding (1710–68). In Bordeaux, Noverre's pupil Jean Dauberval premiered in 1789 *La Fille mal gardée* (*The Ill-Guarded Maiden*), usually called *Vain Precautions* in English, which became the first durable ballet comedy. It introduced the *demi-caractère* dance, which featured what were considered to be "true-to-life" characters. In London, still another pupil, Charles Didelot, created in 1796 *Flore et Zéphyre*. This was the first attempt to bestow on the individual dances within the ballet a certain period and local coloration, and to break the uniformity of step and movement of the corps de ballet by assigning individual tasks to its various members. Later, Didelot thoroughly reformed the ballet school in St. Petersburg, which had existed since 1738. There he also created the first ballets of the Russian national repertory. Among these were the first ballets to be based on the works of the Russian writer Alexandr Pushkin (1799–1837), whose stories continued to be used as ballet libretti for many decades.

In Milan, Salvatore Viganò, who had worked under Dauberval and Didelot and who had choreographed in 1801 the first performance of Beethoven's *Creatures of Prometheus*, was praised by the French writer Stendhal for his thrilling ballets based, among other subjects, on Shakespeare's *Othello* and *Coriolanus*. He was followed by Carlo Blasis, who was more noted as a teacher and theoretician. His *Traité élémentaire, théorique, et pratique de l'art de la danse* (1820; *Elementary Treatise upon the Theory and Practice of the Art of Dancing*) became the standard work of ballet teaching for the 19th century. In 1837 he founded the Imperial Ballet Academy, through which Milan became, with Paris and St. Petersburg, a third ballet centre of world renown.

The Romantic ballet. During the 1830s and '40s the Romantic movement flooded ballet stages with nature spirits, fairies, and sylphids. The cult of the ballerina replaced that of the male dancer, whose last and greatest representative had been the Italian dancer Gaetano Vestris (1729–1808). The techniques of female dancing were greatly improved. Skirts were shortened further, and blocked shoes permitted toe dancing. Choreographers strove for a more expressive vocabulary and to highlight the individual qualities of their dancers.

La Sylphide (1836) stated a main subject of the Romantic ballet, the fight between the real world and the spiritual world. This theme was enhanced and expanded in *Giselle* (1841) and *Ondine* (1843). Paris and London were the taste setters, and it was London that in 1845 witnessed the *Pas de quatre*, for which the French choreographer Jules Perrot brought together, for four performances, four of the greatest ballerinas of the day, the Italians Marie Taglioni (1804–84), Carlotta Grisi (1819–99), and Fanny Cerrito (1817–1909), and Lucile Grahn (1819–1907). After this the decline of Romantic ballet was rapid, at least in these cities. It continued to flourish into the early 1860s, however, in Copenhagen under the choreographer Auguste Bournonville, whose repertoire was kept alive by the Royal Danish Ballet into the second half of the 20th century. Russia, under the French-born Marius Petipa (1819–1910) and his Russian aide Lev Ivanov (1834–1901), built a world-famous ballet culture of its own. Linked at first with Paris, it gradually developed its own balletic idiom from native as well as imported sources. The high point of the classical ballet under the tsars was reached with the St. Petersburg productions of *The Sleeping Beauty* (1890), *The Nutcracker* (1892), and *Swan Lake* (1895), all with music composed by Peter Tchaikovsky, and *Raymonda* (1898), composed by Aleksandr Glazunov (1865–1936). While the ballet prospered in St. Petersburg and Moscow, it waned in Paris. Its ballerinas even appeared in male roles, as in *Coppélia* (1870). In Milan the extravaganzas of Luigi Manzotti (1838–1905) offered anything but dancing while glorifying the progress of mankind through material discoveries and inventions. The 19th century also saw an unprecedented increase in travel and in cross-cultural influences. Many seemingly exotic dance styles arrived on the Western scene. Troupes from as far as India and Japan appeared at expositions in Paris and London, starting a lively interest in folk and ethnic dancing. Ballerinas of the Romantic ballet travelled from one European city to another, from Milan to London to Moscow. The Austrian dancer Fanny Elssler toured the Americas in the early 1840s for two years, visiting Havana twice. The great choreographers, too, went from city to city. The language of dance became a medium of international communication without regard for difference in geography or spoken language.

Russian rise, Western decline

THEATRE AND BALLROOM DANCE

Other dance entertainments of a lighter kind gained immense popularity during the 19th century. In Paris the all-female cancan became the rage. Its electrifying high kicks were shockingly exhibitionistic and titillating. After 1844 it became a feature of the music halls, of revues, and of operetta. It was raised to musical prominence by operetta composer Jacques Offenbach (1819–80) and vividly depicted by the painter Henri de Toulouse-Lautrec (1864–1901). London enjoyed the Alhambra and Empire ballets, which were mostly classical ballets with spectacular productions. But it was America that provided the widest variety. There were patriotic spectacles, popular after the Revolutionary War, such as *The Patriot, or Liberty Asserted,* in which dance figured prominently.

Giraudon—Art Resource/EB Inc

Cancan with "Jane Avril Dancing," oil on cardboard by Henri de Toulouse-Lautrec, 1892. In the Louvre, Paris.

More important and of longer range results were the minstrel shows, extravaganzas, burlesques, and vaudevilles. These represented a confluence of a wide assortment of dance and theatrical influences, especially from black culture. White men affected black faces and black dances, and black men affected the faces and dances of whites. Dances were tap and soft-shoe, the buck-and-wing, and similar routines. Theatrical productions offered all kinds of dance, from European-imported ballets through entirely native exhibitions of female beauty verging on the striptease. American dancers began to establish reputations both in America and Europe. The ballerina Augusta Maywood (1825–76?) was the first American dancer to perform at the Paris Opéra.

During the 19th century there was also an enormous increase in the number of public ballrooms and other dancing establishments in the fast-growing cities of the West. Here were first encountered American imports such as the barn dance, then called the military schottische; the Washington Post, a very rapid two-step in march formation; and the cakewalk, which contorted the body to degrees previously unknown. For the first time Europe found in the New World a new infusion of blood for its dancing veins. The tempo of the dances quickened, reflecting perhaps the quickening pace of life and the great social changes of the century.

The 20th century

Two trends were evident during the first years of the 20th century, before World War I. As if aware of some impending catastrophe, the wealthy society of Europe and the Americas indulged itself to the full in quicker waltzes and faster galops. At the same time, it tried to revive the minuet, gavotte, and pavane, producing only pale and lifeless evocations. There had hardly ever been such a frantic search for new forms, such radical questioning of values previously taken for granted, such a craze among the youth of all nations for individual expression and a more dynamic way of life. All the arts were deeply influenced by the rapid accumulation of discoveries in the physical and social sciences and an increasing awareness of social problems.

New directions in the dance

Overall, it was an incredibly lively time for the dance, which never before had generated so many new ideas or attracted so many people. The ballet was completely rejuvenated under the leadership of Russian impresario Sergey Diaghilev (1872–1929). It inspired some of the foremost composers and painters of the day, becoming the primary theatre platform for the most up-to-date work in the arts. Proponents of another reform movement, "modern dance," took their cue from the American dancer Isadora Duncan to strike in another way at the artificialities that Romantic ballet had generated. It took vigorous roots in Germany, where its expressionistic forms earned it the name *Ausdruckstanz* ("expressionistic dance"). The ballroom dances were thoroughly revolutionized through infusions of new vitality from South American, Creole, and black sources. With the overwhelming popularity of Afro-American jazz, the entire spirit and style of social dancing altered radically, becoming vastly more free, relaxed, and intimate through the following decades.

There was also a renewal of interest in the folk dances that had been the expressions of the common people in past centuries. This was fostered partly through special folk-dance societies, partly through various youth movements that saw that these dances might assist in shaping new community feelings. Theatrical dance of all kinds, from the highly stylized, centuries-old dances of the Orient to exhibitions of naked female flesh, reached new heights of popularity.

DIAGHILEV AND HIS ACHIEVEMENTS

The artistic consequences of Diaghilev's Ballets Russes were enormous. Diaghilev's interest in dance began while he was a member of a small circle of intellectuals in St. Petersburg who fought to bring Russia's arts onto the wider European scene. The painters Alexandre Benois and Léon Bakst were his earliest collaborators.

The Ballets Russes. The Russian ballet troupe that Diaghilev took to Paris in 1909 boasted some of the best dancers from the imperial theatres in St. Petersburg and Moscow. They set all Paris ablaze. No living person could remember ballets of such quality. For the next 20 years the Ballets Russes, which never appeared in Russia, became the foremost ballet company in the West. Diaghilev, who never choreographed a ballet himself, possessed a singular flair for bringing the right people together. He became the focus of the ballet world, striving for the integration of dance, music, visual design, and libretto into a "total work of art" in which no one element dominated the others.

Between 1909 and 1929, the contributions of many of the finest dancers and choreographers and of some of the most avant-garde, style-setting painters and composers made the Diaghilev company the centre of creative artistic activity. The group became a haven for Russian dancers who emigrated after the 1917 Revolution. It was the first large, permanently travelling company that operated on a private basis and catered to a cosmopolitan Western clientele.

Michel Fokine (1880–1942) was the first choreographer to put Diaghilev's ideas into practice. He worked with contemporary composers, notably the Russian Igor Stravinsky

The work of Fokine

(1882–1971) and the Frenchman Maurice Ravel (1875–1937). Stravinsky composed the score for two of Fokine's best known ballets, *L'Oiseau de feu* (*The Firebird;* 1910) and *Petrushka* (1911); both are based on old Russian folktales. He drew also upon many eminent composers of the past, such as the Russians Aleksandr Borodin (1833–87) and Nicolay Rimsky-Korsakov (1844–1908), and the Pole Frédéric Chopin (1810–49). His major scenic artists were Benois and Bakst, whose contributions to theatrical design had influences beyond the sphere of ballet. Among his dancers were the Russians Anna Pavlova (1881–1931), who left after the 1909 season to dance with her own company throughout the West as well as the Orient, and Vaslav Nijinsky (1890–1950), who succeeded Fokine as the company's choreographer. A classic dancer, Nijinsky was an anticlassic choreographer, specializing in turned-in body movements and in unusual footwork. In 1912 Nijinsky choreographed *L'Après-midi d'un faune* (*Afternoon of a Faun*) to music written by the French Impressionist composer Claude Debussy (1862–1918)—it is the only Nijinsky ballet still performed. The following year he created *Le Sacre du printemps* (*The Rite of Spring*) to Stravinsky's music. The unconventional ballet was considered scandalous and nearly caused a riot at its Paris premiere.

After Nijinsky's career was cut short by his insanity, the dancer Léonide Massine (1896–1979) assumed the role of choreographer. He quickly became noted for his wit and the precisely characterizing gestures of his dancers. His musical collaborators included Stravinsky; Manuel de Falla (1876–1946), whose work was full of the flavour of his native Spain; Ottorino Respighi (1879–1936), noted for his musical evocations of Italian landscapes; and Erik Satie (1866–1925), a Frenchman known for his originality and eccentricity. Massine's designers included leading painters of the School of Paris such as André Derain (1880–1954) and Pablo Picasso (1881–1973). Following Diaghilev's death, Massine created a furor in the 1930s with his ballets based on symphonies by Tchaikovsky and Johannes Brahms. It was considered inappropriate to use symphonic music for dance, and the incorporation of the style and movements of modern dance into the plotless ballets added to the controversy.

Another of Diaghilev's choreographers was Nijinsky's sister, Bronisława Nijinska (1891–1972), who became famous for her massive ensemble groupings, used to great effect in *Les Noces* (*The Wedding;* 1923), and her talent for depicting the follies of contemporary society. Diaghilev's last choreographic discovery was the Russian-trained George Balanchine (1904–83). Balanchine's 1928 ballet, *Apollon Musagète,* was the first of many collaborations with Stravinsky and led the way to the final enthronement of neoclassicism as the dominant choreographic style of the following decades.

The continuing tradition. When Diaghilev died his was no longer the only ballet company touring the world. Anna Pavlova's company visited places in Europe, the Americas, Australia, and the Orient that had never heard of, let alone seen, ballet. A troupe assembled by Ida Rubinstein (1885–1960) had Nijinska as a choreographer and Stravinsky and Ravel as composers. The Ballets Suédois featured, from 1920 to 1925, another group of avant-garde, largely French and Italian composers, painters, and writers. New dancers came from the schools in Paris, London, and Berlin that were directed by self-exiled Russian teachers. Important developments took place in London, where Dame Marie Rambert (1888–1982), a Diaghilev dancer, founded the Ballet Rambert, and Ninette de Valois founded the company that became in 1956 the Royal Ballet. In New York, Balanchine set up the School of American Ballet in 1934. From it he drew the dancers for the several companies that led ultimately to the founding of the New York City Ballet in 1948.

The Soviet ballet. Although Diaghilev's achievements were ignored there, the Soviet Union in the 1920s abounded with the daring choreographic experiments of Fyodor Lopukhov (1886–1973) and others. Despite the official imposition of "socialist realism" as the criterion of artistic acceptability in 1932, ballet gained enormous popularity with the Soviet people. They loved their dancers, who were superbly trained by generations of teachers under the leadership of Agrippina Vaganova (1879–1951).

MODERN DANCE

Despite the recovery of ballet from its sterility in the late 19th century, other dancers questioned the validity of an art form so inescapably bound to tradition by its relatively limited vocabulary. They wished to change radically the culture concept of expressive stage dancing. In a period of women's emancipation, women stepped to the front as propagandists for the new dance and toppled the conventions of the academic dance. They advocated a dance that arose from the dancer's innermost impulses to express himself or herself in movement. They took their cues from music or such other sources as ancient Greek vase paintings and the dances of Oriental and American Indian cultures.

The pioneers of this new dance were Isadora Duncan (1877–1927), who stormed across European stages in her loosely flying tunic, inspiring a host of disciples and imitators, and Ruth St. Denis (1877–1968), who surprised American and European audiences with her Oriental-style dances. With her partner Ted Shawn (1891–1972) she founded (1915) Denishawn, which, as a school and performing company, became the cradle of America's early protagonists of modern dance; notable among them were Martha Graham, Doris Humphrey, and Charles Weidman (1901–75).

American and German schools

In the German *Ausdruckstanz* the central figure was Rudolf Laban (1879–1958), who was more a theoretician and teacher than a choreographer. His researches into the physiological impulses to movement and rhythm crystallized in a formidable system of physical expression. His system of dance notation, known most widely as Labanotation, provided the first means for writing down and copyrighting choreographies. His most prolific disciples were Kurt Jooss (1901–79) and Mary Wigman (1886–1973). Jooss became known for his dances containing strong elements of social commentary. Wigman had also studied with Émile Jaques-Dalcroze (1865–1950), who developed eurythmics, a system of movement originally designed to train professional musicians in rhythm. Wigman blended features of both men's techniques into her own new style of dance. When she toured the United States in the 1930s, Americans became aware that they were not alone in their search for new forms of expressive

dance. She left behind one of her closest collaborators, Hanya Holm, who became another major figure on the American scene.

Across the United States schools opened, producing small groups of dancers who performed on college campuses and on small stages in the cities. Each choreographer and company brought different materials, artistic points of view, and performing styles to the dance. Perhaps the single element common to all of the many facets of modern dance was the search for new and valid forms of artistic expression.

NEW RHYTHMS, NEW FORMS

The changes in the social climate that were evident in the new century had a notable influence on the ballrooms.

Latin-American and jazz dances. The younger generation in Europe eagerly took up the more vivacious, dynamic, and passionate social dances from the New World. The turning dances of the 19th century gave way to such walking dances as the two-step, the one-step, or turkey trot, the fox-trot, and the quickstep, performed to the new jagged rhythms. These rhythms were African in origin, whether from the Latin-American tangos and rumbas or from the Afro-American jazz. It is impossible to say how far this music was reduced in intensity from its original forms, but its influence was enormous in shaping the ragtime popular before 1918, the syncopated rhythms and mellower swing that followed it, the acrobatic jitterbug of the 1930s and 1940s, and the rock and roll of the next decades.

Dance contests and codes. After 1912, when ballroom tango became the rage of the dancing world, even elegant hotels invited their clientele to their "tango teas." In fashionable restaurants professional dance couples demonstrated the new styles. In 1892 New York City saw one of the first cakewalk competitions, and in 1907 Nice advertised the first tango contest. After the first world dance competition in 1909, in Paris, this became an annual event, which in 1913 lasted for two weeks. But it was England that acted as arbiter of taste for the new movements in social dance. There the first dance clubs, like the Keen Dancers' Society (later the Boston Club), were founded in 1903. In 1904 the Imperial Society of Teachers of Dancing was established, and in 1910 the periodical *Dancing Times* made its bow. After World War I the English version of the fox-trot was acknowledged as the essence of the internationally acclaimed "English style." Victor Silvester's *Modern Ballroom Dancing* (1928) became the handbook of the dancing world until it was succeeded by Alex Moore's *Ballroom Dancing* (1936). The English style involved strict definitions for the five standard dances—quickstep, waltz, fox-trot, tango, and blues—to which were added after 1945 the Latin-American rumba, samba, calypso, and cha-cha-cha. What was left of the social barriers existing in 1900 between the exclusive and the popular dancing establishments was swept away.

The English style

Many observers were indignant about the changes taking place. Even so liberal a historian as Curt Sachs could not refrain from stating:

> Since the Brazilian *maxixe* of 1890 and the *cakewalk* of 1903 broke up the pattern of turns and glides that dominated the European round dances, our generation has adopted with disquieting rapidity a succession of Central American dances, in an effort to replace what has been lost to modern Europe: multiplicity, power, and expressiveness of movement to the point of grotesque distortion of the entire body.... All [of these dances are] compressed into even movement, all emphasizing strongly the erotic element, and all in that glittering rhythm of syncopated four-four measures classified as *ragtime.* (From Curt Sachs, *op. cit.,* pp. 444–445.)

Sachs went on to note the rapid rise and fall in popularity of individual dances and suggested an impermanence to the entire movement.

Effect on folk dancing. As social dancing spread with the advent of the radio and the phonograph, the regions where genuine folk dancing was practiced became fewer. It continued least corrupted by the new forms in those countries outside the mainstream of Western urbanization and industrialization. Spain maintained its vigorous tradition of flamenco dancing, and in Hungary the composers Béla Bartók (1881–1945) and Zoltán Kodály (1882–1967) collected the remnants of a wealth of folk song and dance folklore. Minority groups such as the Basques in Spain did likewise to maintain their identity against the overpowering influences of their neighbours.

Folk dancing remained a vital reality in the Soviet Union, especially in those European and Asiatic provinces that had distinctive ethnic populations and were far removed from Moscow, Leningrad, and other centres with Western contacts. In the industrial nations of Europe and the Americas, special nationwide councils and societies were founded to preserve the traditional folk dance that was under threat of extinction.

Experiments. Technological progress itself became the subject of dance and dancing. In the Soviet Union, there were experiments during the 1920s with dances created to express urban traffic, the accuracy of machine work, and the grandeur of skyscrapers. In Germany, the painter Oskar Schlemmer (1888–1943) realized his vision of a dance of pure, geometric form in the *Triadisches Ballet* performed in Stuttgart in 1922. In 1926 a sound vision of the technological ages, *Ballet mécanique* (*Mechanical Ballet*), by the American composer George Antheil (1900–59), was scored for mechanical pianos, automobile horns, electric bells, and airplane propellers. It was written not for the live dancer but for an animated film.

THE DANCE SINCE 1945

Dance of all kinds emerged from World War II, more vital and more expansive than before.

Social dance. Postwar social dancing was marked by continuing exuberance and enthusiasm. Dances such as the jitterbug, popular throughout the 1930s and '40s, included lively turns and lifts with rapid footwork. Motion pictures and television helped to spread such rock and roll dances as the twist more rapidly and widely than dances had travelled before. A characteristic of this new generation of jazz-based dances was the lack of bodily contact between the participants, who vibrated their legs, gesticulated with their hands, swung their shoulders, and twitched their heads.

Jazz-based dances

Many observers attempted to draw social implications of all kinds from these dances, which began to spread also among the youth of the Communist countries of Eastern Europe and Asia. Among the more interesting interpretations was that of Frances Rust:

> ... this type of dancing can be thought of as "progression" rather than "regression." Historically speaking, country-dancing of a communal or group nature gives way, with the break up of communities, to partnered-up ballroom dancing with a concentration on couples rather than groups. This, in turn, is now replaced amongst young people by partner-less dancing, which, although individualistic, seems none-the-less, to be rooted in a striving for community feeling and group solidarity (from *Dance in Society;* Routledge and Kegon Paul, 1969).

In the mid-1970s, disco dancing brought a return to dancing with a partner in choreographed steps in dances such as the hustle and the bump. Disco was influenced by modern jazz dancing and became rather athletic, incorporating kicks, turns, and even backflips. Athletic dance moves continued to develop, especially in the 1980s in break dancing, an acrobatic style that featured intricate contortions, mime-like walking moves, and rapid spins on the neck and shoulders. Less complicated dance styles also were found, such as slam dancing, in which the dancers hurled their bodies against each other's, and dances such as the pogo, in which dancers jumped in place to the music's rhythm. Partner dancing never disappeared completely, however, and was especially prominent in the "western-swing" dancing of American country and western music.

Dance in the theatre. On the postwar ballet scene there were no revolutionary developments such as those of Diaghilev earlier in the century. The classical ballet style reigned supreme throughout the West and in the Soviet Union. The leading Russian companies, the Bolshoi Ballet in Moscow and the Kirov Ballet in St. Petersburg, continued the great 19th-century Russian tradition of full-length dramatic ballets. The popularity of ballet and the establishment of many apparently permanent companies made inevitable wide variations in style and content. International tours were resumed on a large scale. There was also considerable interaction in terms of style and personnel between ballet and modern dance. This was especially true at the New York City Ballet, founded in the late 1940s by George Balanchine and Lincoln Kirstein. The company presented many new works by choreographers such as Jerome Robbins, William Dollar, and Sir Frederick Ashton (the latter principal choreographer and director of Britain's Royal Ballet), but it was Balanchine's style that dominated the company through great ballets such as *The Nutcracker* (1954) and *Don Quixote* (1965) and more abstract works such as *Agon* (1957) and *Jewels* (1967). After Balanchine's death in 1983, Robbins and dancer-choreographer Peter Martins became ballet masters in chief and continued the company's tradition and at the same time introduced new works.

New York City Ballet

Another leading company was the American Ballet Theatre, founded in 1939. Its repertoire combined a broad range of works by choreographers such as Antony Tudor and Eliot Feld and balanced classical ballets with established contemporary pieces and newly commissioned works. After the retirement of co-directors Lucia Chase and Oliver Smith in 1980, the great Latvian-born U.S. dancer Mikhail Baryshnikov was named artistic director.

The development of modern dance continued in the work of innovative dancer-choreographers who formed their own companies to explore new styles of dance. Martha Graham's expressive dance centred on mythic and legendary themes, whether ancient, as in *Primitive Mysteries* (1931) and *Clytemnestra* (1958), or modern, as in *Appalachian Spring* (1944). One of Graham's dancers, Merce Cunningham, concentrated on abstract movement that minimized emotional content and experimented with techniques for achieving purity of movement, including arranging sequences of dance steps by flipping a coin. Twyla Tharp was another experimental choreographer whose early work reduced dance to its most fundamental level—movement through open areas, often without music. Her later work melded classical ballet and jazz with modern dance. A different perspective was offered by Arthur Mitchell, who left the New York City Ballet to found the Dance Theatre of Harlem, a company with strong roots in classical ballet.

The American musical theatre benefitted from the techniques of theatrical dance forms. Choreographers of ballet and modern dance also created works for musical comedy. Agnes deMille choreographed *Rodeo* (1942) for the Ballet Russe de Monte Carlo and later created many modern works for the American Ballet Theatre; she also choreographed the stage and film versions of Rodgers and Hammerstein's *Oklahoma!* (1943 and 1955, respectively) and the stage versions of *Carousel* (1945) and *Paint Your Wagon* (1951). Jerome Robbins contributed excellent works for the stage in *The King and I* (1951) and *Fiddler on the Roof* (1967), as well as the stage and film versions of *West Side Story* (1957 and 1961).

Companies presenting dances from India, Sri Lanka, Bali, and Thailand were no longer considered exotic on Western stages, and their influences contributed to both ballet and modern dance. Numerous ensembles sprang up, their repertoires based on traditional national dances adapted for the stage. Many were modelled on the Moiseyev folk-dance company of the Soviet Union, which had attracted large audiences during its frequent European and American tours. Similar companies existed in several eastern European countries, in Israel, and in some African nations, as well as in Brazil, Mexico, and the Philippines.

From the beginning of the 20th century, the dance scene became extremely multifaceted and colourful. If some of its manifestations appeared contradictory, that could be regarded as proof of its vitality. No other century granted dance so prominent a role among its social activities. Indications of this prominence included a vast increase in dance research and writing, the opening of colleges and universities in America to special dance faculties, and establishment in the Soviet Union of institutes for the study of choreography. And dance notation promised great advances in recording specific choreographies and as a basic linguistic tool in dance education.

BIBLIOGRAPHY. CURT SACHS, *A World History of the Dance* (1937, reprinted 1965; originally published in German, 1933), the most comprehensive, systematic, and factual history of dance in all its epochs and forms, with special emphasis on its earliest beginnings and close attention to dance accompaniment; W.F. RAFFÉ, *Dictionary of the Dance* (1965, reissued 1975), detailed descriptions of the particular dances, their background, and history; ANATOLE CHUJOY and P.W. MANCHESTER (eds.), *The Dance Encyclopedia,* rev. ed. (1967), a collection of articles on all forms of dancing—particularly detailed in its coverage of ballet, including entries on specific productions, artistic biographies, and histories of ballet in various countries; HORST KOEGLER, *The Concise Oxford Dictionary of Ballet*, 2nd ed. (1982), a comprehensive reference work; LINCOLN KIRSTEIN, *Dance: A Short History of Classic Theatrical Dancing* (1935, reprinted 1970), a very thorough book on the pre-balletic forms of dance as well as classic theatrical dance; WALTER SORELL, *The Dance Through the Ages* (1967), a general, readable survey of the worldwide dance scene from prehistoric times through today, with superb pictures of ancient and modern dance; A.H. FRANKS, *Social Dance: A Short History* (1963), the first attempt at relating the origins and developments of the most important social dance forms to their social environment; FRANCES RUST, *Dance in Society* (1969), a study giving documentary evidence of the social dances and their relationships to the changing structures of society, with emphasis on the English scene and the teenage explosion in dance during the 1960s.

Dante

Dante Alighieri (1265–1321) is Italy's greatest poet and also one of the towering figures in western European literature. He is best known for his monumental epic poem, *La commedia,* later named *La divina commedia* (*The Divine Comedy*). This great work of medieval literature is a profound Christian vision of man's temporal and eternal destiny. On its most personal level, it draws on the poet's own experience of exile from his native city of Florence; on its most comprehensive level, it may be read as an allegory, taking the form of a journey through hell, purgatory, and paradise. The poem amazes by its array of learning, its penetrating and comprehensive analysis of contemporary problems, and its inventiveness of language and imagery. By choosing to write his poem in Italian rather than in Latin, Dante decisively influenced the course of literary development. Not only did he lend a voice to the emerging lay culture of his own country, but Italian became the literary language in western Europe for several centuries. In addition to poetry Dante wrote important theoretical works ranging from discussions of rhetoric to moral philosophy and political thought. He was fully conversant with the classical tradition, drawing for his own purposes on such writers as Virgil, Cicero, and Boethius. But, most unusual for a layman, he also had an impressive command of the most recent scholastic philosophy and of theology. His learning and his personal involvement in the heated political controversies of his age led him to the composition of *De monarchia,* one of the major tracts of medieval political philosophy.

Early life and the Vita nuova. Most of what is known about Dante's life he has told himself. He was born in Florence in 1265 under the sign of Gemini (between May 21 and June 20) and remained devoted to his native city all his life. Dante describes how he fought as a cavalryman against the Ghibellines, a banished Florentine party supporting the imperial cause. He also speaks of his great teacher Brunetto Latini and his gifted friend Guido Cavalcanti, of the poetic culture in which he made his first artistic ventures, his poetic indebtedness to Guido Guinizelli, the origins of his family in his great-great-grandfather, Cacciaguida, whom the reader meets in the central cantos of the *Paradiso* (and from whose wife the family name, Alighieri, derived), and, going back even further, of the pride that he felt in the fact that his distant ancestors were descendants of the Roman soldiers who settled along the banks of the Arno.

Alinari—Mansell/Art Resource

"Dante and His Work" by Domenico di Michelino, 1465. In Florence cathedral.

Yet Dante has little to say about his more immediate family. There is no mention of his father or mother, brother or sister in *The Divine Comedy.* A sister is possibly referred to in the *Vita nuova,* and his father is the subject of insulting sonnets exchanged in jest between Dante and his friend Forese Donati. Because Dante was born in 1265 and the exiled Guelfs, to whose party Dante's family adhered, did not return until 1266, Dante's father apparently was not a figure considerable enough to warrant exile. Dante's mother died when he was young, certainly before he was 14. Her name was Bella, but of which family is unknown. Dante's father then married Lapa di Chiarissimo Cialuffi and they produced a son, Francesco, and a daughter, Gaetana. Dante's father died prior to 1283, since at that time Dante, having come into his majority, was able as an orphan to sell a credit owned by his father. The elder Alighieri left his children a modest yet comfortable patrimony of property in Florence and in the country. About this time Dante married Gemma Donati, to whom he had been betrothed since 1277.

Dante's life was shaped by the long history of conflict between the imperial and papal partisans called, respectively, Ghibellines and Guelfs. Following the middle of the 13th century the antagonisms were brutal and deadly, with each side alternately gaining the upper hand and inflicting gruesome penalties and exile upon the other. In 1260 the Guelfs, after a period of ascendancy, were defeated in the battle of Montaperti (*Inferno* X, XXXII), but in 1266 a force of Guelfs, supported by papal and French armies, was able to defeat the Ghibellines at Benevento, expelling them forever from Florence. This meant that Dante grew up in a city brimming with postwar pride and expansionism, eager to extend its political control throughout Tuscany. Florentines compared themselves with Rome and the civilization of the ancient city-states.

Ghibellines and Guelfs

Not only did Florence extend its political power, but it was ready to exercise intellectual dominance as well. The leading figure in Florence's intellectual ascendancy was a returning exile, Brunetto Latini. When in the *Inferno* Dante describes his encounter with his great teacher, this is not to be regarded as simply a meeting of one pupil with his master but rather as an encounter of an entire generation with its intellectual mentor. Latini had awakened a new public consciousness in the prominent figures of a younger generation, including Guido Cavalcanti, Forese Donati, and Dante himself, encouraging them to put their knowledge and skill as writers to the service of their city or country. Dante readily accepted the Aristotelian assumption that man is a social (political) being. Even in the *Paradiso* (VIII.117) Dante allows as being beyond any possible dispute the notion that things would be far worse for man were he not a member of a city-state.

Influence of Brunetto Latini

A contemporary historian, Giovanni Villani, characterized Latini as the "initiator and master in refining the Florentines and in teaching them how to speak well, and how to guide our republic according to political philosophy [*la politica*]." Despite the fact that Latini's most important book, *Li Livres dou Trésor* (1262–66; *The Tresor*), was written in French (Latini had passed his years of exile in France), its culture is Dante's culture; it is a repository of classical citation. The first part of Book II contains one of the early translations in a modern European vernacular of Aristotle's *Ethics.* On almost every question or topic of philosophy, ethics, and politics Latini freely quotes from Cicero and Seneca. And, almost as frequently, when treating questions of government, he quotes from the book of Proverbs, as Dante was to do. The Bible, as well as the writings of Aristotle, Cicero, and Seneca, as represented in Latini's work, were the mainstays of Dante's early culture.

Of these Rome presents the most inspiring source of identification. The cult of Cicero began to develop alongside that of Aristotle; Cicero was perceived as not only preaching but as fully exemplifying the intellectual as citizen. A second Roman element in Latini's legacy to become an important part of Dante's culture was the love of glory, the quest for fame through a wholehearted devotion to excelling. For this reason, in the *Inferno* (XV) Latini is praised for instructing Dante in the means by which man makes himself immortal, and in his farewell words Latini commits to Dante's care his *Tresor,* through which he trusts his memory will survive.

Dante was endowed with remarkable intellectual and aesthetic self-confidence. By the time he was 18, as he himself says in the *Vita nuova,* he had already taught himself the art of making verse (chapter III). He sent an early sonnet, which was to become the first poem in the *Vita nuova,* to the most famous poets of his day. He received several responses, but the most important one came from Cavalcanti, and this was the beginning of their great friendship.

Influence of Cavalcanti

As in all meetings of great minds the relationship between Dante and Cavalcanti was a complicated one. In chapter XXX of the *Vita nuova* Dante states that it was through Cavalcanti's exhortations that he wrote his first book in Italian rather than in Latin. Later, in the *Convivio,* written in Italian, and in *De vulgari eloquentia,* written in Latin, Dante was to make one of the first great Renaissance defenses of the vernacular. His later thinking on these matters grew out of his discussions with Cavalcanti, who prevailed upon him to write only in the vernacular. Because of this intellectual indebtedness, Dante dedicated his *Vita nuova* to Cavalcanti—to his best friend (*primo amico*).

Later, however, when Dante became one of the priors of Florence, he was obliged to concur with the decision to exile Cavalcanti, who contracted malaria during the banishment and died in August 1300. In the *Inferno* (X) Dante composed a monument to his great friend, and it is as heartrending a tribute as his memorial to Latini. In both cases Dante records his indebtedness, his fondness, and his appreciation of their great merits, but in each he is equally obliged to record the facts of separation. In order to save himself, he must find (or has found) other, more powerful aesthetic, intellectual, and spiritual sponsorship than that offered by his old friends and teachers.

Beatrice

One of these spiritual guides, for whom Cavalcanti evidently did not have the same appreciation, was Beatrice, a figure in whom Dante created one of the most celebrated fictionalized women in all of literature. In keeping with the changing directions of Dante's thought and the vicissitudes of his career, she, too, underwent enormous changes in his hands—sanctified in the *Vita nuova,* demoted in the canzoni (poems) presented in the *Convivio,* only to be returned with more profound comprehension in *The Divine Comedy* as the woman credited with having led Dante away from the "vulgar herd."

La vita nuova (*c.* 1293; *The New Life*) is the first of two collections of verse that Dante made in his lifetime, the other being the *Convivio.* Each is a *prosimetrum,* that is, a work composed of verse and prose. In each case the prose is a device for binding together poems composed over about a 10-year period. The *Vita nuova* brought together Dante's poetic efforts from before 1283 to roughly 1292–93; the *Convivio,* a bulkier and more ambitious work, contains Dante's most important poetic compositions from just prior to 1294 to the time of *The Divine Comedy.*

The *Vita nuova,* which Dante called his *libello,* or small book, is a remarkable work. It contains 42 brief chapters with commentaries on 25 sonnets, one *ballata,* and four canzoni; a fifth canzone is left dramatically interrupted by Beatrice's death. The prose commentary provides the frame story, which does not emerge from the poems themselves (it is, of course, conceivable that some were actually written for other occasions than those alleged). The story is simple enough, telling of Dante's first sight of Beatrice when both are nine years of age, her salutation when they are 18, Dante's expedients to conceal his love for her, the crisis experienced when Beatrice withholds her greeting, Dante's anguish that she is making light of him, his determination to rise above anguish and sing only of his lady's virtues, anticipations of her death (that of a young friend, the death of her father, and Dante's own premonitory dream), and finally the death of Beatrice, Dante's mourning, the temptation of the sympathetic *donna gentile* (a young woman who temporarily replaces Beatrice), Beatrice's final triumph and apotheosis, and, in the last chapter, Dante's determination to write at some later time about her "that which has never been written of any woman."

The impersonal style of the *Vita nuova*

Yet with all of this apparently autobiographical purpose the *Vita nuova* is strangely impersonal. The circumstances it sets down are markedly devoid of any historical facts or descriptive detail (thus making it pointless to engage in too much debate as to the exact historical identity of Beatrice). The language of the commentary also adheres to a high level of generality. Names are rarely used—Cavalcanti is referred to three times as Dante's "best friend"; Dante's sister is referred to as "she who was joined to me by the closest proximity of blood." On the one hand Dante suggests the most significant stages of emotional experience, but on the other he seems to distance his descriptions from strong emotional reactions. The larger structure in which Dante arranged poems written over a 10-year period and the generality of his poetic language are indications of his early and abiding ambition to go beyond the practices of local poets.

Dante's intellectual development and public career. A second contemporary poetic figure behind Dante was Guido Guinizelli, the poet most responsible for altering the prevailing local, or "municipal," kind of poetry. Guinizelli's verse provided what Cavalcanti and Dante were looking for—a remarkable sense of joy contained in a refined and lucid aesthetic. What increased the appeal of his poetry was its intellectual, even philosophical, content. His poems were written in praise of the lady and of *gentilezza,* the virtue that she brought out in her admirer. The conception of love that he extolled was part of a refined and noble sense of life. It was Guinizelli's influence that was responsible for the poetic and spiritual turning point of the *Vita nuova.* As reported in chapters XVII to XXI, Dante experienced a change of heart, and rather than write poems of anguish, he determined to write poems in praise of his lady, especially the canzone "Donne ch'avete intelletto d'amore" ("Ladies Who Have Understanding of Love"). This canzone is followed immediately by the sonnet "Amore e 'l cor gentil sono una cosa" ("Love and the Noble Heart Are the Same Thing"), the first line of which is clearly an adaptation of Guinizelli's "Al cor gentil ripara sempre amore" ("In Every Noble Heart Love Finds Its Home"). This was the beginning of Dante's association with a new poetic style, the *dolce stil nuovo* ("the sweet new style"), the significance of which—the simple means by which it transcended the narrow range of the more regional poetry—he dramatically explains in the *Purgatorio* (XXIV).

Dolce stil nuovo

This interest in philosophical poetry led Dante into another great change in his life, which he describes in the *Convivio.* Looking for consolation following the death of Beatrice, Dante reports that he turned to philosophy, particularly to the writings of Boethius and Cicero. But what was intended as a temporary reprieve from sorrow became a lifelong avocation and one of the most crucial intellectual events in Dante's career. The *donna gentile* of the *Vita nuova* was transformed into Lady Philosophy, who soon occupied all of Dante's thoughts. He began attending the religious schools of Florence in order to hear disputations on philosophy, and within a period of only 30 months "the love of her [philosophy] banished and destroyed every other thought." In his poem "Voi che 'ntendendo il terzo ciel movete" ("You Who Through Intelligence Move the Third Sphere") he dramatizes this conversion from the sweet old style, associated with Beatrice and the *Vita nuova,* to the rigorous, even severe, new style associated with philosophy. This period of study gave expression to a series of canzoni that were eventually to form the poetic basis for the philosophic commentary of the *Convivio.*

Another great change was Dante's more active political involvement in the affairs of the commune. In 1295 he became a member of the guild of physicians and apothecaries (to which philosophers could belong), which opened

his way to public office. But he entered the public arena at a most perilous time in the city's politics. As it had been during the time of the Guelf and Ghibelline civil strife, in the 1290s Florence once again became a divided city. The ruling Guelf class of Florence became divided into a party of "Blacks," led by Corso Donati, and a party of "Whites," to which Dante belonged. The Whites gained the upper hand and exiled the Blacks.

Political activity

There is ample information concerning Dante's activities following 1295. In May 1300 he was part of an important embassy to San Gimignano, a neighbouring town, whose purpose it was to solidify the Guelf league of Tuscan cities against the mounting ambitions of the new and embattled pope Boniface VIII. When Dante was elected to the priorate in 1300, he presumably was already recognized as a spokesman for those in the commune determined to resist the Pontiff's policies. Dante thus experienced a complete turnabout in his attitudes concerning the extent of papal power. The hegemony of the Guelfs—the party supporting the Pope—had been restored in Florence in 1266 by an alliance forged between the forces of France and the papacy. By 1300, however, Dante had come to oppose the territorial ambitions of the Pope, and this in turn provided the intellectual motivation for another, even greater change: Dante, the Guelf moderate, would in time, through his firsthand experience of the ill effects of papal involvement in political matters, become in the *Convivio,* in the later polemical work the *Monarchia,* and most importantly throughout *The Divine Comedy,* one of the most fervently outspoken defenders of the position that the empire does not derive its political authority from the pope.

Events, moreover, propelled Dante into further opposition to papal policies. A new alliance was formed between the papacy, the French (the brother of King Philip IV, Charles of Valois, was acting in concert with Boniface), and the exiled Black Guelfs. When Charles of Valois wished permission to enter Florence, the city itself was thrown into political indecision. In order to ascertain the nature of the Pope's intentions, an embassy was sent to Rome to discuss these matters with him. Dante was one of the emissaries, but his quandary was expressed in the legendary phrase "If I go, who remains; if I remain, who goes?" Dante was outmaneuvered. The Pope dismissed the other two legates and detained Dante. In early November 1301 the forces of Charles of Valois were permitted entry to Florence. That very night the exiled Blacks surreptitiously reentered Florence and for six days terrorized the city. Dante learned of the deception at first in Rome and then more fully in Siena. In January 1302 he was called to appear before the new Florentine government and, failing to do so, was condemned, along with three other former priors, for crimes he had not committed. Again failing to appear, on March 10, 1302, Dante and 14 other Whites were condemned to be burned to death. Thus Dante suffered the most decisive crisis of his life. In *The Divine Comedy* he frequently and powerfully speaks of this rupture; indeed, he makes it the central dramatic act toward which a long string of prophecies points. But it is also Dante's purpose to show the means by which he triumphed over his personal disaster, thus making his poem into a true "divine comedy."

Exile, the Convivio, and the De monarchia. Information about Dante's early years in exile is scanty; nevertheless, enough is known to provide a broad picture. It seems that Dante at first was active among the exiled White Guelfs in their attempts to seek a military return. These efforts proved fruitless. Evidently Dante grew disillusioned with the other Florentine outcasts, the Ghibellines, and was determined to prove his worthiness by means of his writings and thus secure his return. These are the circumstances that led him to compose *Il convivio* (*c.* 1304–07; "The Banquet").

The plan of the *Convivio*

Dante projected a work of 15 books, 14 of which would be commentaries on different canzoni. He completed only four of the books. The finished commentaries in many ways go beyond the scope of the poems, becoming a compendium of instruction with much of the random display of an amateur in philosophy. Dante's intention in the *Convivio,* as in *The Divine Comedy,* was to place the challenging moral and political issues of his day into a suitable ethical and metaphysical framework.

Book I of the *Convivio* is in large part a stirring and systematic defense of the vernacular. (The unfinished *De vulgari eloquentia* [*c.* 1304–07; *Concerning Vernacular Eloquence*], a companion piece, presumably written in coordination with Book I, is primarily a practical treatise in the art of poetry based upon an elevated poetic language.) Dante became the great advocate of its use and in the final sentence of Book I he accurately predicts its glorious future:

> This shall be the new light, the new sun, which shall rise when the worn-out one shall set, and shall give light to them who are in shadow and in darkness because of the old sun, which does not enlighten them.

The revolution Dante described was nothing less than the twilight of the predominantly clerical Latin culture and the emergence of a lay, vernacular urban literacy. Dante saw himself as the philosopher-mediator between the two, helping to educate a newly enfranchised public readership. The Italian literature that Dante heralded was soon to become the leading literature and Italian the leading literary language of Europe, and they would continue to be that for more than three centuries.

In the *Convivio* Dante's mature political and philosophical system is nearly complete. In this work Dante makes his first stirring defense of the imperial tradition and, more specifically, of the Roman Empire. He introduces the crucial concept of *horme,* that is, of an innate desire that prompts the soul to return to God. But it requires proper education through examples and doctrine. Otherwise it can become misdirected toward worldly aims and society torn apart by its destructive power. In the *Convivio* Dante establishes the link between his political thought and his understanding of human appetite: given the pope's craving for worldly power, at the time there existed no proper spiritual models to direct the appetite toward God; and given the weakness of the empire, there existed no law sufficient to exercise a physical restraint on the will. For Dante this explains the chaos into which Italy had been plunged, and it moved him, in hopes of remedying these conditions, to take up the epic task of *The Divine Comedy.*

But a political event occurred that at first raised tremendous hope but then plunged Dante into still greater disillusionment. In November 1308 Henry, the count of Luxembourg, was elected king of Germany, and in July 1309 the French pope, Clement V, who had succeeded Boniface, declared Henry to be king of the Romans and invited him to Rome, where in time he would be crowned Holy Roman emperor in St. Peter's Basilica. The possibility of once again having an emperor electrified Italy; and among the imperial proponents was Dante, who saw approaching the realization of an ideal that he had long held: the coming of an emperor pledged to restore peace while also declaring his spiritual subordination to religious authority. Within a short time after his arrival in Italy in 1310 Henry VII's great appeal began to fade. He lingered too long in the north, allowing his enemies to gather strength. Foremost among the opposition to this divinely ordained moment, as Dante regarded it, was the commune of Florence.

The prospect of a new emperor

During these years Dante wrote important political epistles—evidence of the great esteem in which he was held throughout Italy, of his personal authority, as it were—in which he exalted Henry, urging him to be diligent, and condemned Florence. In subsequent action, however, which was to remind Dante of Boniface's duplicity, Clement himself turned against Henry. This action prompted one of Dante's greatest polemical treatises, his *De monarchia* (*c.* 1313; *On Monarchy*) in which he expands the political arguments of the *Convivio.* In the embittered atmosphere caused by Clement's deceit Dante turned his argumentative powers against papal insistence on its superiority over the political ruler, that is, against the argument that the empire derived its political authority from the pope. In the final passages of the *Monarchia* Dante writes that the ends designed by Providence for

man are twofold: one end is the bliss of this life, which is conveyed in the figure of the earthly paradise; the other is the bliss of eternal life, which is embodied in the image of a heavenly paradise. Yet despite their different ends, these two purposes are not unconnected. Dante concludes his *Monarchia* by assuring his reader that he does not mean to imply "that the Roman government is in no way subject to the Roman pontificate, for in some ways our mortal happiness is ordered for the sake of immortal happiness." Dante's problem was that he had to express in theoretical language a subtle relationship that might be better conveyed by metaphoric language and historical example. Surveying the history of the relationship between papacy and empire, Dante pointed with approval to specific historical examples, such as Constantine's good will toward the church. Dante's disappointment in the failed mission of Henry VII derived from the fact that Henry's original sponsor was apparently Pope Clement and that conditions seemed to be ideal for reestablishing the right relationship between the supreme powers.

Dante's view of imperial and papal authority

The Divine Comedy. Dante's years of exile were years of difficult peregrinations from one place to another—as he himself repeatedly says, most effectively in *Paradiso* [XVII], in Cacciaguida's moving lamentation that "bitter is the taste of another man's bread and . . . heavy the way up and down another man's stair." Throughout his exile Dante nevertheless was sustained by work on his great poem, possibly begun prior to 1308 and completed just before his death in 1321. In addition, in his final years Dante was received honourably in many noble houses in the north of Italy, most notably by Guido Novello da Polenta, the nephew of the remarkable Francesca, in Ravenna. There at his death Dante was given an honourable burial attended by the leading men of letters of the time, and the funeral oration was delivered by Guido himself.

The plot of *The Divine Comedy* is simple: a man, generally assumed to be Dante himself, is miraculously enabled to undertake an ultramundane journey, which leads him to visit the souls in Hell, Purgatory, and Paradise. He has two guides: Virgil, who leads him through the *Inferno* and *Purgatorio,* and Beatrice, who introduces him to *Paradiso.* Through these fictional encounters taking place from Good Friday evening in 1300 through Easter Sunday and slightly beyond, Dante learns of the exile that is awaiting him (which had, of course, already occurred at the time of the writing). This device allowed Dante not only to create a story out of his pending exile but also to explain the means by which he came to cope with his personal calamity and to offer suggestions for the resolution of Italy's troubles as well. Thus, the exile of an individual becomes a microcosm of the problems of a country, and it also becomes representative of the fall of man. Dante's story is thus historically specific as well as paradigmatic.

The basic structural component of *The Divine Comedy* is the canto. The poem consists of 100 cantos, which are grouped together into three sections, or canticles, *Inferno, Purgatorio,* and *Paradiso.* Technically there are 33 cantos in each canticle and one additional canto, contained in the *Inferno,* which serves as an introduction to the entire poem. For the most part the cantos range from about 136 to about 151 lines. The poem's rhyme scheme is the terza rima (*aba, bcb, cdc,* etc.) Thus, the divine number of three is present in every part of the work.

Comparison with the *Odyssey* and the *Aeneid*

Dante's *Inferno* differs from its great classical predecessors in both position and purpose. In Homer's *Odyssey* (Book XII) and Virgil's *Aeneid* (Book VI) the visit to the land of the dead occurs in the middle of the poem because in these centrally placed books the essential values of life are revealed. Dante, while adopting the convention, transforms the practice by beginning his journey with the visit to the land of the dead. He does this because his poem's spiritual pattern is not classical but Christian: Dante's journey to Hell represents the spiritual act of dying to the world, and hence it coincides with the season of Christ's own death. (In this way, Dante's method is similar to that of Milton in *Paradise Lost,* where the flamboyant but defective Lucifer and his fallen angels are presented first.) The *Inferno* represents a false start during which Dante, the character, must be disabused of harmful values that somehow prevent him from rising above his fallen world. Despite the regressive nature of the *Inferno,* Dante's meetings with the roster of the damned are among the most memorable moments of the poem: the Neutrals, the virtuous pagans, Francesca da Rimini, Filipo Argenti, Farinata degli Uberti, Piero delle Vigne, Brunetto Latini, the simoniacal popes, Ulysses, and Ugolino impose themselves upon the reader's imagination with tremendous force.

The visit to Hell is, as Virgil and later Beatrice explain, an extreme measure, a painful but necessary act before real recovery can begin. This explains why the *Inferno* is both aesthetically and theologically incomplete. For instance, readers frequently express disappointment at the lack of dramatic or emotional power in the final encounter with Satan in canto XXXIV. But because the journey through the *Inferno* primarily signifies a process of separation and thus is only the initial step in a fuller development, it must end with a distinct anticlimax. In a way this is inevitable because the final revelation of Satan can have nothing new to offer: the sad effects of his presence in human history have already become apparent throughout the *Inferno.*

Purgatory as the realm of spiritual renewal

In the *Purgatorio* the protagonist's painful process of spiritual rehabilitation commences; in fact, this part of the journey may be considered the poem's true moral starting point. Here the pilgrim Dante subdues his own personality in order that he may ascend. In fact, in contrast to the *Inferno,* where Dante is confronted with a system of models that needs to be discarded, in the *Purgatorio* few characters present themselves as models; all of the penitents are pilgrims along the road of life. Dante, rather than being an awed if alienated observer, is an active participant. If the *Inferno* is a canticle of enforced and involuntary alienation, in which Dante learns how harmful were his former allegiances, in the *Purgatorio* he comes to accept as most fitting the essential Christian image of life as a pilgrimage. As Beatrice in her magisterial return in the earthly paradise reminds Dante, he must learn to reject the deceptive promises of the temporal world.

Despite its harsh regime, the *Purgatorio* is the realm of spiritual dawn, where larger visions are entertained. Whereas in only one canto of the *Inferno* (VII), in which Fortuna is discussed, is there any suggestion of philosophy, in the *Purgatorio,* historical, political, and moral vistas are opened up. It is, moreover, the great canticle of poetry and the arts. Dante meant it literally when he proclaimed, after the dreary dimensions of Hell: "But here let poetry rise again from the dead." There is only one poet in Hell proper and not more than two in the *Paradiso,* but in the *Purgatorio* the reader encounters the musicians Casella and Belacqua and the poet Sordello and hears of the fortunes of the two Guidos, Guinizelli and Cavalcanti, the painters Cimabue and Giotto, and the miniaturists. In the upper reaches of Purgatory, the reader observes Dante reconstructing his classical tradition and then comes even closer to Dante's own great native tradition (placed higher than the classical tradition) when he meets Forese Donati, hears explained—in an encounter with Bonagiunta da Lucca—the true resources of the *dolce stil nuovo,* and meets with Guido Guinizelli and hears how he surpassed in skill and poetic mastery the reigning regional poet, Guittone d'Arezzo. These cantos resume the line of thought presented in the *Inferno* (IV), where among the virtuous pagans Dante announces his own program for an epic and takes his place, "sixth among that number," alongside the classical writers. In the *Purgatorio* he extends that tradition to include Statius (whose *Thebaid* did in fact provide the matter for the more grisly features of the lower inferno), but he also shows his more modern tradition originating in Guinizelli. Shortly after his encounter with Guinizelli comes the long-awaited reunion with Beatrice in the earthly paradise. Thus, from the classics Dante seems to have derived his moral and political understanding as well as his conception of the epic poem, that is, a framing story large enough to encompass the most important issues of his day, but it was from his native tradition that he acquired the philosophy of love that forms the Christian matter of his poem.

The rejection of Virgil

This means of course that Virgil, Dante's guide, must give way to other leaders, and in a canticle generally de-

void of drama the rejection of Virgil becomes the single dramatic event. Dante's use of Virgil is one of the richest cultural appropriations in literature. To begin, in Dante's poem he is an exponent of classical reason. He is also a historical figure and is presented as such in the *Inferno* (I): "... once I was a man, and my parents were Lombards, both Mantuan by birth. I was born *sub Julio,* though late in his time, and I lived in Rome under the good Augustus, in the time of the false and lying gods." Virgil, moreover, is associated with Dante's homeland (his references are to contemporary Italian places), and his background is entirely imperial. (Born under Julius Caesar, he extolled Augustus Caesar.) He is presented as a poet, the theme of whose great epic sounds remarkably similar to that of Dante's poem: "I was a poet and sang of that just son of Anchises who came from Troy after proud Ilium was burned." So, too, Dante sings of the just son of a city, Florence, who was unjustly expelled, and forced to search, as Aeneas had done, for a better city, in his case the heavenly city.

Virgil is a poet whom Dante had studied carefully and from whom he had acquired his poetic style, the beauty of which has brought him much honour. But Dante had lost touch with Virgil in the intervening years, and when the spirit of Virgil returns it is one that seems weak from long silence. But the Virgil that returns is more than a stylist; he is the poet of the Roman Empire, a subject of great importance to Dante, and he is a poet who has become a *saggio,* a sage, or moral teacher.

Though an exponent of reason, Virgil has become an emissary of divine grace, and his return is part of the revival of those simpler faiths associated with Dante's earlier trust in Beatrice. And yet, of course, Virgil by himself is insufficient. It cannot be said that Dante rejects Virgil; rather he sadly found that nowhere in Virgil's work, that is, in his consciousness, was there any sense of personal liberation from the enthrallment of history and its processes. Virgil had provided Dante with moral instruction in survival as an exile, which is the theme of his own poem as well as Dante's, but he clung to his faith in the processes of history, which, given their culmination in the Roman Empire, were deeply consoling. Dante, on the other hand, was determined to go beyond history because it had become for him a nightmare.

In the *Paradiso* true heroic fulfillment is achieved. Dante's poem gives expression to those figures from the past who seem to defy death. Their historical impact continues and the totality of their commitment inspires in their followers a feeling of exaltation and a desire for identification. In his encounters with such characters as his great-great-grandfather Cacciaguida and SS. Francis, Dominic, and Bernard, Dante is carried beyond himself. The *Paradiso* is consequently a poem of fulfillment and of completion. It is the fulfillment of what is prefigured in the earlier canticles. Aesthetically it completes the poem's elaborate system of anticipation and retrospection.

Assessment and influence. The recognition and the honour that were the due of Dante's *Divine Comedy* did not have to await the long passage of time: by the year 1400 no fewer than 12 commentaries devoted to detailed expositions of its meaning had appeared. Giovanni Boccaccio wrote a life of the poet and then in 1373–74 delivered the first public lectures on *The Divine Comedy* (which means that Dante was the first of the moderns whose work found its place with the ancient classics in a university course). Dante became known as the *divino poeta,* and in a splendid edition of his great poem published in Venice in 1555 the adjective was applied to the poem's title; thus, the simple *Commedia* became *La divina commedia,* or *The Divine Comedy.*

The *Commedia* becomes *La divina commedia*

Even when the epic lost its appeal and was replaced by other art forms (the novel, primarily, and the drama) Dante's own fame continued. In fact, his great poem enjoys the kind of power peculiar to a classic: successive epochs have been able to find reflected in it their own intellectual concerns. In the post-Napoleonic 19th century, readers identified with the powerful, sympathetic, and doomed personalities of the *Inferno.* In the early 20th century they found the poem to possess an aesthetic power of verbal realization independent of and at times in contradiction to its structure and argument. Later readers have been eager to show the poem to be a polyphonic masterpiece, as integrated as a mighty work of architecture, whose different sections reflect and, in a way, respond to one another. Dante created a remarkable repertoire of types in a work of vivid mimetic presentations, as well as a poem of great stylistic artistry in its prefigurations and correspondences. Moreover, he incorporated in all of this important political, philosophical, and theological themes and did so in a way that shows moral wisdom and lofty ethical vision.

Dante's *Divine Comedy* is a poem that has flourished for more than 650 years: in the simple power of its striking imaginative conceptions it has continued to astonish generations of readers; for more than a hundred years it has been a staple in all higher educational programs in the Western world; and it has continued to provide guidance and nourishment to the major poets of our own times. William Butler Yeats called Dante "the chief imagination of Christendom"; and T.S. Eliot elevated Dante to a preeminence shared by only one other poet in the modern world, William Shakespeare: "[They] divide the modern world between them. There is no third." In fact, they rival one another in their creation of types that have entered into the world of reference and association of modern thought. Like Shakespeare, Dante created universal types from historical figures, and in so doing he considerably enhanced the treasury of modern myth.

MAJOR WORKS

Because Dante lived and worked long before book printing began, it is not possible to discuss first editions of his works. The following begins with a list of early printed editions of his works in the original languages.

INDIVIDUAL WORKS: *La commedia* (1472); *Vita nuova* (1576).

LYRIC POETRY: *Canzoni e madrigali di Dante, di Mess. Gino da Pistoja e di Giraldo Novello* (1518); *Rime di diversi antichi autori toscani in dieci libri* (1532).

TREATISES: *Convivio di Dante Alighieri fiorentino* (1490); *De vulgari eloquentia libri duo* (1577); *Dantis Aligherii Florentini Monarchia* (1740).

LATIN ECLOGUES: *I versi latini di Giovanni del Virgilio e di Dante Allighieri* (1845).

RECOMMENDED MODERN EDITIONS: *La commedia secondo l'antica vulgata,* ed. by Giorgio Petrocchi (1966–67); *La divina commedia,* ed. by Natalino Sapegno, 3rd ed. (1985), with excellent commentary; *The Divine Comedy of Dante Alighieri,* trans. by John D. Sinclair (1958), with superb small essays for each canto; *The Divine Comedy,* trans. with a commentary by Charles S. Singleton (1970–75), the most useful work in English, published in the Bollingen series.

La vita nuova, ed. by Michele Barbi (1932), a critical edition; *Dante's Vita Nuova,* trans. by Mark Musa, new ed. (1973).

Rime della "Vita nuova" e della giovinezza, ed. by Michele Barbi and F. Maggini (1956); *Rime della maturità e dell'esilio,* ed. by Michele Barbi and V. Pernicone (1969); *Rime,* ed. by Gianfranco Contini (1965); *Dante's Lyric Poetry,* ed. and trans. by K. Foster and P. Boyde (1967).

Il convivio, 2nd ed., ed. by G. Busnelli, G. Vandelli, and Antonio E. Quaglio (1968); *Dante's Convivio,* trans. by William Walrond Jackson (1909).

De vulgari eloquentia, ed. by Aristide Marigo (1957); *Dante's Treatise "De Vulgari Eloquentiâ,"* trans. by A.G. Ferrers Howell (1890); *Literary Criticism of Dante Alighieri,* trans. and ed. by Robert S. Haller (1973).

Monarchia, ed. by Pier Giorgio Ricci (1965); *On World Government, or, De Monarchia,* trans. by Herbert W. Schneider, 2nd rev. ed. (1957).

Dante and Giovanni del Virgilio, Including a Critical Edition of the Text of Dante's "Eclogae Latinae" and of the Poetic Remains of Giovanni del Virgilio, ed. by Philip H. Wicksteed and Edmund G. Gardner (1902).

COLLECTED WORKS: *Le opere di Dante: testo critico della società dantesca italiana,* ed. by Michele Barbi *et al.,* 2nd ed. (1960); *Le opere di Dante Alighieri,* ed. by E. Moore and Paget Toynbee, 5th ed. (1963).

BIBLIOGRAPHY

Biographies: RICARDO J. QUINONES, *Dante Alighieri* (1979, reprinted 1985), an overview; CECIL GRAYSON (ed.), *The World of Dante: Essays on Dante and His Times* (1980); and WILLIAM ANDERSON, *Dante the Maker* (1980), a critical biographical study, with the emphasis on Dante's creative processes. See also PATRICK BOYDE, *Dante, Philomythes and Philosopher: Man in the Cosmos* (1981), an examination of Dante's intellectual concerns.

Commentaries: For extracts from early commentaries, see GUIDO BIAGI *et al.* (eds.), *La Divina Commedia nella figurazione artistica e nel secolare commento* (1921–40), issued in separate parts, and its useful bibliography. Modern commentaries on *The Divine Comedy* include those by GIUSEPPE VANDELLI, CARLO GRABHER, MANFREDI PORENA, ATTILIO MOMIGLIANO, and NATALINO SAPEGNO in their respective editions of *La divina commedia.* See also FRANCESCO MAZZONI, *Saggio di un nuovo commento alla Divina Commedia* (1967). For English-speaking readers, the commentary of CHARLES H. GRANDGENT (ed.), *La Divina Commedia di Dante Alighieri* (1933; rev. ed. by CHARLES S. SINGLETON, 1972), is excellent; as is that of CHARLES S. SINGLETON (trans. and ed.), *The Divine Comedy* (1970–75). See also GEORGE HOLMES, *Dante* (1980), a brief study; MARK MUSA, *Advent at the Gates* (1974), a study of seven cantos; and DAVID NOLAN (ed.), *Dante Commentaries: Eight Studies of the Divine Comedy* (1977), and *Dante Soundings: Eight Literary and Historical Essays* (1981).

Introductory works: Of the general works available to English-speaking readers, see especially ERNEST HATCH WILKINS and THOMAS GODDARD BERGIN, *A Concordance to the Divine Comedy of Dante Alighieri* (1965). EDWARD S. SHELDON and ALAIN C. WHITE, *Concordanza delle opere italiane in prosa e del Canzoniere di Dante Alighieri* (1905, reprinted 1969 with *Supplementary Concordance to the Minor Italian Works of Dante,* comp. by LEWIS H. GORDON); and EDWARD KENNARD RAND and ERNEST HATCH WILKINS, *Dantis Alagherii Operum Latinorum Concordantiae,* to the Latin works (1912, reprinted 1970), are also useful. PAGET TOYNBEE, *A Dictionary of Proper Names and Notable Matters in the Works of Dante,* new ed., rev. by CHARLES S. SINGLETON (1968), is invaluable. Excellent introductions to Dante include UMBERTO COSMO, *A Handbook to Dante Studies* (1947, reprinted 1978; originally published in Italian, 1947); MICHELE BARBI, *Life of Dante* (1954, reprinted 1966; originally published in Italian, 1933); and THOMAS GODDARD BERGIN, *Dante* (1965, reprinted 1976). Also useful are NICOLA ZINGARELLI, *La vita, i tempi e le opere di Dante,* 3rd ed., 2 vol. (1931); and ALDO VALLONE, *Dante,* 2nd ed. (1981). Essential information is found in *Codice diplomatico dantesco,* ed. by RENATO PIATTOLI, 2nd ed. (1950); and in *Enciclopedia dantesca,* 2nd ed., 5 vol. (1984).

General studies: EDWARD MOORE, *Studies in Dante,* 4 vol. (1896–1917, reprinted with new introductory matter ed. by COLIN HARDIE, 1969); PAGET TOYNBEE, *Dante Studies* (1921); BENEDETTO CROCE, *The Poetry of Dante* (1922, reissued 1971; originally published in Italian, 1920); T.S. ELIOT, *Dante* (1929; reprinted 1974); JOHN FRECCERO (ed.), *Dante: A Collection of Critical Essays* (1965); UBERTO LIMENTANI (ed.), *The Mind of Dante* (1965); OXFORD DANTE SOCIETY, *Centenary Essays on Dante* (1965); WILLIAM J. DE SUA and GINO RIZZO (eds.), *A Dante Symposium* (1965); FRANCESCO MAZZONI, *Contributi di filologia dantesca* (1966).

Bibliographies: PAUL COLOMB DE BATINES, *Bibliografia dantesca,* trans. from the French, 2 vol. in 3 (1845–46), supplemented by GUIDO BIAGI, *Giunte e correzioni inediti alla Bibliografia dantesca* (1888); continued also in CARLO F. CARPELLINI, *Della letteratura dantesca degli ultimi venti anni dal 1845 a tutto il 1865* (1866); CORNELL UNIVERSITY LIBRARY, *Catalogue of the Dante Collection,* comp. by THEODORE WESLEY KOCH, 2 vol. (1898–1900), and *Catalogue of the Dante Collection Additions 1898–1920,* comp. by MARY FOWLER (1921); and GIULIANO MAMBELLI, *Gli annali delle edizioni dantesche* (1931, reprinted 1965). For post-World War II studies, see ALDO VALLONE, *Gli studi danteschi dal 1940 al 1949* (1950); and ENZO ESPOSITO, *Gli studi danteschi dal 1950 al 1964* (1965). Annual bibliographies of Dante studies published in the United States are printed in *Dante Studies* (annual), published by the Dante Society of America (founded 1881). Bodies specializing in Dante studies have been established in many countries. Apart from the Società Dantesca Italiana (founded 1888), of special interest to English-speaking readers is the Oxford Dante Society (founded 1876).

(R.J.Q.)

Darwin

Charles Darwin was an English naturalist whose theory of evolution by natural selection became the foundation of modern evolutionary studies. An affable country gentleman, Darwin shocked Victorian society of the 19th century by suggesting that humans shared a common ancestry with animals. However, his nonreligious biology appealed to a rising class of professional scientists, and by the time of his death evolutionary imagery had spread through all of science, literature, and politics.

Darwin formulated his bold theory in private in 1837–39, after returning from a voyage around the world aboard HMS *Beagle,* but it was not until two decades later that he finally gave it full public expression in *On the Origin of Species* (1859), a book that has deeply influenced modern Western society and thought.

Early life and education. Charles Robert Darwin was born on February 12, 1809, in Shrewsbury, Shropshire. He was the second son of society doctor Robert Waring Darwin and of Susannah Wedgwood, daughter of the Unitarian pottery industrialist Josiah Wedgwood. Darwin's other grandfather, Erasmus Darwin, a freethinking physician, was author of *Zoonomia; or, The Laws of Organic Life* (1794–96). Darwin's mother died when he was eight, and he was cared for by his three elder sisters. The boy stood in awe of his overbearing father, but he hated the rote learning of classics at the traditional Anglican Shrewsbury School, where he studied between 1818 and 1825. Science was then considered dehumanizing in English public schools, and for dabbling in chemistry Darwin was condemned by his headmaster (and nicknamed "Gas" by his schoolmates).

Scientific studies at Edinburgh

His father, considering the 16-year-old a wastrel interested only in game shooting, sent him to study medicine at Edinburgh University in 1825. Later in life, Darwin gave the impression that he had learned little during his two years at Edinburgh. In fact, it was a formative experience, for there was no better science education in a British university. More crucially, the university's radical students exposed the teenager to the latest Continental sciences. Edinburgh attracted English Dissenters who were barred from graduating at the Anglican universities of Oxford and Cambridge, and at student societies Darwin heard freethinkers deny the divine design of human facial anatomy and argue that animals shared all the human mental faculties. As he collected sea slugs and sea pens on nearby shores, he was accompanied by Robert Edmond Grant, a radical evolutionist and disciple of the French biologist Jean-Baptiste Lamarck. An expert on sponges, Grant became Darwin's mentor, teaching him about the growth and relationships of primitive marine invertebrates, which Grant believed held the key to unlocking the mysteries surrounding the origin of more complex creatures.

The young Darwin learned much in Edinburgh's rich intellectual environment, but not medicine. His freethinking father, shrewdly realizing that the church was a better calling for an aimless naturalist, switched him to Christ's College, Cambridge, in 1828. Darwin was now educated as an Anglican gentleman. He took his horse, indulged his drinking, shooting, and beetle-collecting passions with other squires' sons, and managed 10th place in the Bachelor of Arts degree in 1831. Here he was shown the conservative side of botany by a young professor, the Reverend John Stevens Henslow.

Fired by Alexander von Humboldt's *Personal Narrative of Travels,* Darwin jumped at Henslow's suggestion of a voyage to South America aboard a rebuilt brig, HMS *Beagle.* Darwin would sail as a self-financed companion to the aristocratic 26-year-old captain, Robert Fitzroy, who planned to survey the coast of Patagonia and to return three "savages" previously brought to England from Tierra del Fuego and Christianized. Darwin equipped himself with weapons, books, and advice from London Zoo's experts on preserving carcasses. The *Beagle* sailed from England on December 27, 1831.

The *Beagle* voyage. The circumnavigation of the globe would be the making of the 22-year-old Darwin. Five years of physical hardship and mental rigour—imprisonment within a ship's walls, offset by wide-open opportunities in the Brazilian jungles and the Andes Mountains—were to give Darwin a new seriousness. The hardship was immediate: a tormenting seasickness. And so was his questioning: on the Cape Verde Islands (January 1832), the sailor saw bands of oyster shells running through local rocks, suggesting that the land was rising in places, falling in others. At Bahia (now Salvador), Brazil, the luxuriance of the rainforest left Darwin's mind in "a chaos of delight." Months were spent in Rio de Janeiro amid shimmering tropical splendour, full of "gaily-coloured" flatworms, and the collector himself became "red-hot with Spiders." But nature had its own evils, and Darwin always remembered with a shudder the parasitic ichneumon wasp, which stored caterpillars to be eaten alive by its grubs. He would later consider this to be evidence against the beneficent design of nature.

On the River Plate (Río de la Plata) in July 1832, he found Montevideo, Uruguay, in a state of rebellion and joined armed sailors to retake the rebel-held fort. At Bahía Blanca, Argentina, gauchos told him of their extermination of the Pampas "Indians." Beneath the veneer of human civility, genocide seemed the rule on the frontier. For a sensitive young man, fresh from Christ's College, this was disturbing. Darwin's contact with "untamed" humans on Tierra del Fuego in December 1832 unsettled him more. How great, wrote Darwin, the "difference between savage & civilized man is.—It is greater than between a wild & [a] domesticated animal." God had evidently created humans in a vast cultural range—and yet, judging by the Christianized savages aboard, even the "lowest" races were capable of improvement. Darwin was tantalized, and always he niggled for explanations.

Fossil discoveries in South America

His fossil discoveries raised more questions. Darwin's periodic trips over two years to the cliffs at Bahía Blanca and farther south at Port St. Julian yielded huge bones of ex-

Darwin's rhea (*Rhea pennata*), drawing by John Gould for *Zoology of the Voyage of H.M.S. Beagle* (1838–43), from specimens collected by Charles Darwin.
The Natural History Museum, London

tinct mammals—relics, he assumed, of rhinoceroses, mastodons, cow-sized armadillos, and giant ground sloths. Fossil extraction became a romance for Darwin. It pushed him into thinking of the primeval world and what had caused these giant beasts to die out.

After the *Beagle* surveyed the Falkland Islands, and after Darwin had packed away at Port Desire (Puerto Deseado), Argentina, the partially gnawed bones of a new species of small rhea (see the colour print), the ship sailed up the west coast of South America to Valparaíso, Chile. Here Darwin climbed 4,000 feet (1,200 metres) into the Andean foothills and marveled at the forces that could raise such mountains. The forces themselves became tangible in Valdivia, Chile, on February 20, 1835, as he lay on a forest floor: the ground shook, and the violence of the earthquake and ensuing tidal wave was enough to destroy the great city of Concepción, whose rubble Darwin walked through. But what intrigued him was the seemingly insignificant: the local mussel beds, all dead, were now lying above high tide. The continent was thrusting itself up, a few feet at a time. Darwin imagined the eons it had taken to raise the fossilized trees in sandstone (once seashore mud) to 7,000 feet (2,100 metres), where he found them. (See his own sketch.) He began thinking in terms of deep time.

Bird species on the Galapagos Islands

They left Peru on the circumnavigation home in September 1835. First Darwin landed on the "frying hot" Galapagos Islands. These were volcanic prison islands, crawling with marine iguanas and giant tortoises. Contrary to legend, these islands never provided Darwin's "eureka" moment. Although he noted that the mockingbirds differed on four islands and tagged his specimens accordingly, he failed to label his other birds—what he thought were wrens, "gross-beaks," finches, and oriole relatives—by island. Nor did Darwin collect tortoise specimens, even though local prisoners believed that each island had its distinct race.

The "home-sick heroes" returned via Tahiti, New Zealand, and Australia. By April 1836, when the *Beagle* made the Cocos (Keeling) Islands in the Indian Ocean, Darwin already had his theory of reef formation. He imagined (correctly) that these reefs grew on sinking mountain rims. The delicate coral built up, compensating for the drowning land, so as to remain within optimal heat and lighting conditions. At the Cape of Good Hope, Darwin talked with the astronomer Sir John Herschel, possibly about Charles Lyell's theory of gradual geologic change and perhaps about how it entailed a new problem, the "mystery of mysteries," the simultaneous change of fossil life.

On the last leg of the voyage, Darwin finished his 770-page diary, wrapped up 1,750 pages of notes, drew up 12 catalogs of his 5,436 skins, bones, and carcasses—and still he wondered: Was each Galapagos mockingbird a naturally produced variety? Why did ground sloths become extinct? He sailed home with problems enough to last him a lifetime. When he landed in October 1836, the vicarage had faded, the gun had given way to the notebook, and the supreme theorizer—who would always move from small causes to big outcomes—had the courage to look beyond the conventions of his own Victorian culture for new answers.

Evolution by natural selection: the London years. With his voyage over and with a £400 annual allowance from his father, Darwin now settled down among the urban gentry as a gentleman geologist. He befriended Lyell, and he discussed the rising Chilean coastline as a new fellow of the Geological Society in January 1837. Darwin became well known through his diary's publication as *Journal of Researches into the Geology and Natural History of the Various Countries Visited by H.M.S. Beagle* (1839). With a £1,000 Treasury grant, obtained through the Cambridge network, he employed the best experts and published their descriptions of his specimens in his *Zoology of the Voyage of H.M.S. Beagle* (1838–43). Darwin's star had risen, and he was now lionized in London.

Formulating the theory in secret

It was in these years of civil unrest following the First Reform Act (1832) that Darwin devised his theory of evolution. Radical Dissenters were denouncing the church's monopoly on power—attacking an Anglican status quo that rested on miraculous props: the supposed supernatural creation of life and society. Darwin had Unitarian roots, and his breathless notes show how his radical Dissenter's understanding of equality and antislavery framed his image of mankind's place in nature: "Animals—whom we have made our slaves we do not like to consider our equals.—Do not slave holders wish to make the black man other kind?" Some radicals questioned whether each animal was uniquely "designed" by God when all vertebrates shared a similar structural plan. The polymathic Charles Babbage—of calculating machine fame—made God a divine programmer, preordaining life by means of natural law rather than ad hoc miracle. It was the ultra-Whig way,

Eye-Sketch of the Structure and Composition of the Mountains, Copiapó River valley, Chile, by Charles Darwin, *c.* 1835. Striations drawn in the Andes peaks represent successive rock deposits, ranging from hard granites and porphyritic rocks to soft gypsums, in which Darwin found fossils of extinct marine organisms.

and in 1837 Darwin, an impeccable Whig reformer who enjoyed Babbage's soirees, likewise accepted that "the Creator creates by . . . laws."

The experts' findings sent Darwin to more heretical depths. At the Royal College of Surgeons, the eminent anatomist Richard Owen found that Darwin's Pampas fossils were nothing like rhinoceroses and mastodons. They were huge extinct armadillos, anteaters, and sloths, which suggested that South American mammals had been replaced by their own kind according to some unknown "law of succession." At the Zoological Society, ornithologist John Gould announced that the Galapagos birds were not a mixture of wrens, finches, and "gross-beaks" but all ground finches, differently adapted. (See Gould's colour print of a Darwin's finch.) Darwin examined Fitzroy's collection to discover that each island had its representative finch. How had they all diverged from mainland colonists? By this time Darwin was living near his freethinking brother, Erasmus, in London's West End, and their dissident dining circle provided the perfect milieu for Darwin's ru-

minations. Darwin adopted "transmutation" (evolution, as it is now called), perhaps because of his familiarity with it through the work of his grandfather and Robert Grant. Nonetheless, it was abominated by the Cambridge clerics as a bestial, if not blasphemous, heresy that would corrupt mankind and destroy the spiritual safeguards of the social order. Thus began Darwin's double life, which would last for two decades.

For two years he filled notebooks with jottings. There was an intensity and doggedness to it. He searched for the causes of extinction, accepted life as a branching tree (not a series of escalators, the old idea), tackled island isolation, and wondered whether variations appeared gradually or at a stroke. He dismissed the Lamarckian idea of a force driving life inexorably upward. Indeed, there was no "upward": Darwin became relativistic, sensing that life was spreading outward into niches, not standing on a ladder. There was no way of ranking humans and bees, no yardstick of "highness": man was no longer the crown of creation.

Personal distress

Heart palpitations and stomach problems were affecting Darwin by September 1837. Stress sent him to the Highlands of Scotland in 1838, where he diverted himself studying the "parallel roads" of Glen Roy, so like the raised beaches in Chile. But the sickness returned as he continued chipping at the scientific bedrock of a cleric-dominated society. The "whole [miraculous] fabric totters & falls," he jotted. Darwin had a right to be worried. Were his secret discovered, he would stand accused of social abandon. His notes began mooting disarming ploys: "Mention persecution of early astronomers." Behind his respectable facade at the Geological Society lay a new contempt for the divines' providential shortsightedness. The president, the Reverend William Whewell, "says length of days adapted to duration of sleep of man.!!!" he jotted. What "arrogance!!"

Mankind: there was the crux. Darwin wrote humans and society into the evolutionary equation from the start. He saw the social instincts of troop animals developing into morality and studied the humanlike behaviour of orangutans at the zoo. With avant-garde society radicalized, Darwin moved into his own ultraradical phase in 1838—even suggesting that belief in God was an ingrained tribal survival strategy: "love of [the] deity [is an] effect of [the brain's] organization. Oh you Materialist!" he mocked himself. In a day when a gentleman's character had to be above reproach, Darwin's notes had a furtive ring. None of this could become known—yet. The rich careerist—admitted to the prestigious Athenaeum Club in 1838 and the Royal Society in 1839—had too much to lose.

As a sporting gent from the shires, Darwin queried breeders about the way they changed domestic dogs and fancy pigeons by spotting slight variations and accentuating them through breeding. But he saw the complete congruity between the way nature operated and the way fanciers produced new breeds only upon reading the economist Thomas Malthus's *Essay on the Principle of Population* in September 1838. Darwin realized that population explosions would lead to a struggle for resources and that the ensuing competition would weed out the unfit. It was an idea he now applied to nature. (He had previously thought that animal populations remained stable in the wild.) Darwin called his modified Malthusian mechanism "natural selection." Nature was equally uncharitable, went the argument: overpopulated, it experienced a fierce struggle, and from all manner of chance variations, good and bad, the best, "the surviving one of ten thousand trials," won out, endured, and thus passed on its improved trait. This was the way a species kept pace with the Lyellian evolution of the Earth.

Marriage to Emma Wedgwood

Darwin was a born list maker. In 1838 he even totted up the pros and cons of taking a wife—and married his cousin Emma Wedgwood (1808–96) in 1839. He rashly confided his thoughts on evolution, evidently shocking her. By now, Darwin accepted the notion that even mental traits and instincts were randomly varying, that they were the stuff for selection. But he saw from Emma's reaction that he must publicly camouflage his views. Although the randomness and destructiveness of his evolutionary system—with thousands dying so that the "fittest" might survive—left little room for a personally operating benign deity, Darwin still believed that God was the ultimate lawgiver of the universe. In 1839 he shut his last major evolution notebook, his theory largely complete.

The squire naturalist in Downe. Darwin drafted a 35-page sketch of his theory of natural selection in 1842 and expanded it in 1844, but he had no immediate intention of publishing it. In 1842, increasingly shunning society, he had moved his family to the isolated village of Downe, in Kent, at the "extreme edge of [the] world." (It was in fact only 16 miles [26 km] from central London.) Here, living in a former parsonage, Down House, he emulated the lifestyle of his clerical friends. His seclusion was complete: from now on he ran his days like clockwork, with set periods for walking, napping, reading, and nightly backgammon. He fulfilled his parish responsibilities, eventually helping to run the local Coal and Clothing Club for the labourers. His work hours were given over to bees, flowers, and barnacles and to his books on coral reefs and South American geology, three of which in 1842–46 secured his reputation as a career geologist.

He rarely mentioned his secret. When he did, notably to the Kew Gardens botanist Joseph Dalton Hooker, Darwin said that believing in evolution was "like confessing a murder." Darwin, nervous and nauseous, trying spas and quack remedies (even tying plate batteries to his heaving stomach), understood the conservative clerical morality. He was sensitive to the offense he might cause. He was also immensely wealthy: by the late 1840s the Darwins had £80,000 invested; he was an absentee landlord of two large Lincolnshire farms; and in the 1850s he plowed tens of thousands of pounds into railway shares.

From 1846 to 1854, Darwin added to his credibility as an

expert on species by pursuing a detailed study of all known barnacles. Intrigued by their sexual differentiation, he discovered that some females had tiny degenerate males clinging to them. This sparked his interest in the evolution of diverging male and female forms from an original hermaphrodite creature. Four monographs on such an obscure group made him a world expert and gained him the Royal Society's Royal Medal in 1853.

On the Origin of Species. England became quieter and more prosperous in the 1850s, and by mid-decade the professionals were taking over, instituting exams and establishing a meritocracy. The changing social composition of science—typified by the rise of the freethinking biologist Thomas Henry Huxley—promised a better reception for Darwin. Huxley, the philosopher Herbert Spencer, and other outsiders were opting for a secular nature in the rationalist Westminster Review and deriding the influence of "parsondom." Darwin had himself lost the last shreds of his belief in Christianity with the tragic death of his oldest daughter, Annie, from typhoid in 1851.

New freethinking scientists

The world was becoming safer for Darwin and his theory: mid-Victorian England was more stable than the "hungry Thirties" or turbulent 1840s. In 1854 he solved his last major problem, the forking of genera to produce new evolutionary branches. He used an industrial analogy familiar from the Wedgwood factories, the division of labour: competition in nature's overcrowded marketplace would favour variants that could exploit different aspects of a niche. Species would diverge on the spot, like tradesmen in the same tenement.

After speaking to Huxley and Hooker at Downe in April 1856, Darwin began writing a triple-volume book, tentatively called *Natural Selection,* which was designed to crush the opposition with a welter of facts. Darwin now had immense scientific and social authority, and his place in the parish was assured when he was sworn in as a justice of the peace in 1857. Encouraged by Lyell, Darwin continued writing through the birth of his 10th and last child, the mentally retarded Charles Waring Darwin (born in 1856, when Emma was 48). Whereas in the 1830s Darwin had thought that species remained perfectly adapted until the environment changed, he now believed that every new variation was imperfect and that perpetual struggle was the rule.

Darwin had finished a quarter of a million words by June 18, 1858. That day he received a letter from Alfred Russel Wallace, an English socialist and specimen collector working in the Malay Archipelago, sketching a similar-looking theory. Darwin, fearing loss of priority, accepted Lyell's and Hooker's solution: they read joint extracts from Darwin's and Wallace's works at the Linnean Society on July 1, 1858. Darwin was away, sick, grieving for his tiny son who had died from scarlet fever, and thus he missed the first public presentation of the theory of natural selection. It was an absenteeism that would mark his later years.

Darwin hastily began an "abstract" of *Natural Selection,* which grew into a more accessible book, *On the Origin of Species by Means of Natural Selection; or, The Preservation of Favoured Races in the Struggle for Life.* Suffering from a terrible bout of nausea, Darwin, now 50, was secreted away at a spa on the desolate Yorkshire moors when the book was sold to the trade on November 22, 1859. He still feared the worst and sent copies to the experts with self-effacing letters ("how you will long to crucify me alive"). It was like "living in Hell," he said about these months.

Reaction to the book

The book did distress his Cambridge patrons, but they were marginal to science now. However, radical Dissenters were sympathetic, as were the rising London biologists and geologists, even if few actually adopted Darwin's cost-benefit approach to nature. The newspapers drew the one conclusion that Darwin had specifically avoided: that humans had evolved from apes, and that Darwin was denying mankind's immortality. A sensitive Darwin, making no personal appearances, let Huxley, by now a good friend, manage this part of the debate. The pugnacious Huxley did so with enthusiasm. He wrote three reviews of *Origin of Species,* defended human evolution at the Oxford meeting of the British Association for the Advancement of Science in 1860 (when Bishop Samuel Wilberforce jokingly asked whether the apes were on Huxley's grandmother's or grandfather's side), and published his own book on human evolution, *Evidence as to Man's Place in Nature* (1863). What Huxley championed was Darwin's evolutionary naturalism, his nonmiraculous assumptions, which pushed biological science into previously taboo areas and increased the power of Huxley's professionals. And it was they who gained the Royal Society's Copley Medal for Darwin in 1864.

The patriarch in his home laboratory. Long periods of debilitating sickness in the 1860s left the craggy, bearded Darwin thin and ravaged. He once vomited for 27 consecutive days. Down House was an infirmary where illness was the norm and Emma the attendant nurse. She was a shield, protecting the patriarch, cosseting him. Darwin was a typical Victorian in his racial and sexual stereotyping—however dependent on his redoubtable wife, he still thought women inferior; and, although a fervent abolitionist, he still considered blacks a lower race. But few outside of the egalitarian socialists challenged these prejudices, and Darwin, immersed in a competitive Whig culture and enshrining its values in his science, had no time for socialism.

The house was also a laboratory, where Darwin continued experimenting and revamping the *Origin* through six editions. Although quietly swearing by "my deity 'Natural Selection,'" he answered critics by reemphasizing other causes of change—for example, the effects of continued use of an organ—and he bolstered the Lamarckian belief that such alterations through excessive use might be passed on. In *The Variation of Animals and Plants Under Domestication* (1868) he marshaled the facts and explored the causes of variation in domestic breeds. The book answered critics such as George Douglas Campbell, the 8th duke of Argyll, who loathed Darwin's blind, accidental process of variation and envisaged the appearance of "new births" as goal-directed. By showing that fanciers picked from the gamut of naturally occurring variations to produce the tufts and topknots on their fancy pigeons, Darwin undermined this providential explanation.

Seeking the causes of variation

In 1867 the engineer Fleeming Jenkin argued that any single favourable variation would be swamped and lost by back-breeding within the general population. No mechanism was known for inheritance, and so in the *Variation* Darwin devised his hypothesis of "pangenesis" to explain the discrete inheritance of traits. He imagined that each tissue of an organism threw out tiny "gemmules," which passed to the sex organs and permitted copies of themselves to be made in the next generation. But Darwin's cousin Francis Galton failed to find these gemmules in rabbit blood, and the theory was dismissed.

Darwin was adept at taking seemingly intractable subjects and making them test cases for "natural selection." Hence the book that appeared after the *Origin* was, to everyone's surprise, *On the Various Contrivances by Which British and Foreign Orchids Are Fertilised by Insects* (1862). Here he showed that the orchid's beauty was not a piece of floral whimsy "designed" by God to please humans but honed by selection to attract insect cross-pollinators. The petals guided the bees to the nectaries, and pollen sacs were deposited exactly where they could be removed by a stigma of another flower.

But why the importance of cross-pollination? Darwin's botanical work was always subtly related to his evolutionary mechanism. He believed that cross-pollinated plants would produce fitter offspring than self-pollinators, and he used considerable ingenuity in conducting thousands of crossings to prove the point. The results appeared in *The Effects of Cross and Self Fertilisation in the Vegetable Kingdom* (1876). His next book, *The Different Forms of Flowers on Plants of the Same Species* (1877), was again the result of long-standing work into the way evolution in some species favoured different male and female forms of flowers to facilitate outbreeding. Darwin had long been sensitive to the effects of inbreeding because he was himself married to a Wedgwood cousin, as was his sister Caroline. He agonized over its debilitating consequence for his five sons. Not that he need have worried, for they fared

well: William became a banker, Leonard an army major, George the Plumian Professor of Astronomy at Cambridge, Francis a reader in botany at Cambridge, and Horace a scientific instrument maker.

The private man and the public debate. Through the 1860s natural selection was already being applied to the growth of society. A.R. Wallace saw cooperation strengthening the moral bonds within primitive tribes. Advocates of social Darwinism, in contrast, complained that modern civilization was protecting the "unfit" from natural selection. Francis Galton argued that particular character traits—even drunkenness and genius—were inherited and that "eugenics," as it would come to be called, would stop the genetic drain. The trend to explain the evolution of human races, morality, and civilization was capped by Darwin in his two-volume *The Descent of Man, and Selection in Relation to Sex* (1871). The book was authoritative, annotated, and heavily anecdotal in places. The two volumes were discrete, the first discussing the evolution of civilization and human origins among the Old World monkeys. (Darwin's depiction of a hairy human ancestor with pointed ears led to a spate of caricatures; see the cartoon.) The second volume responded to critics such as Argyll, who doubted that the iridescent hummingbird's plumage had any function—or any Darwinian explanation. Darwin argued that female birds were choosing mates for their gaudy plumage. Such "sexual selection" happened among humans, too. With primitive societies accepting diverse notions of beauty, aesthetic preferences, he believed, could account for the origin of the human races.

The Descent of Man

Darwin finished another long-standing line of work. Since studying the moody orangutans at London Zoo in 1838, through the births of his 10 children (whose facial contortions he duly noted), Darwin had been fascinated by expression. As a student he had heard the attacks on the idea that peoples' facial muscles were designed by God to express their unique thoughts. Now his photographically illustrated *The Expression of the Emotions in Man and Animals* (1872) expanded the subject to include the rages and grimaces of asylum inmates, all to show the continuity of emotions and expressions between humans and animals.

The gentle Darwin elicited tremendous devotion. A protective circle formed around him, locked tight by Huxley and Hooker. Nor did Darwin forget it: he helped raise £2,100 to send a fatigued Huxley on holiday in 1873, and his pestering resulted in the impecunious Wallace being added to the Civil List in 1881. Darwin was held in awe by many, the more so because he was rarely seen. And when he was seen—for example, by the Harvard philosopher John Fiske, a privileged visitor to Down House in 1873—he was found to be "the dearest, sweetest, loveliest old grandpa that ever was."

MR. BERGH TO THE RESCUE.

THE DEFRAUDED GORILLA. "That *Man* wants to claim my Pedigree. He says he is one of my Descendants."
MR. BERGH. "Now, Mr. DARWIN, how could you insult him so?"

Satirical cartoon by Thomas Nast, from *Harper's Weekly*, August 19, 1871.

Darwin wrote his autobiography between 1876 and 1881. It was composed for his grandchildren, rather than for publication, and it was particularly candid on his dislike of Christian myths of eternal torment. To people who inquired about his religious beliefs, however, he would say only that he was an agnostic (a word coined by Huxley in 1869).

The treadmill of experiment and writing gave so much meaning to his life. But, as he wrapped up his final, long-term interest, publishing *The Formation of Vegetable Mould, Through the Action of Worms* (1881), the future looked bleak. Such an earthy subject was typical Darwin: Suffering from angina, he looked forward to joining the worms, contemplating "Down graveyard as the sweetest place on earth." He had a seizure in March 1882 and died of a heart attack on April 19, 1882. Influential groups wanted a grander commemoration than a funeral in Downe, something better for the gentleman naturalist who had delivered the "new Nature" into the new professionals' hands. Huxley, who by taking over the public debate had preserved Darwin's reputation of "sweet and gentle nature blossomed into perfection," as a newspaper put it, convinced the canon of Westminster Abbey to bury the diffident agnostic there. And so Darwin was laid to rest with full ecclesiastical pomp on April 26, 1882, attended by the new nobility of science and the state.

Looking forward to death

MAJOR WORKS. Book-length works by Charles Darwin (presented in chronological order of publication) include: *Journal of Researches into the Geology and Natural History of the Various Countries Visited by H.M.S. Beagle* (1839); *The Structure and Distribution of Coral Reefs* (1842); *Geological Observations on the Volcanic Islands, Visited During the Voyage of H.M.S. Beagle* (1844); *Geological Observations on South America* (1846); *A Monograph on the Fossil Lepadidae; or, Pedunculated Cirripedes of Great Britain* (1851); *A Monograph on the Sub-Class Cirripedia,* 2 vol. Death

During the latter half of the 20th century, death has become a strangely popular subject. Before that time, perhaps rather surprisingly, it was a theme largely eschewed in serious scientific, and to a lesser extent, philosophical speculations. It was neglected in biological research and, being beyond the physician's ministrations, was deemed largely irrelevant by medical practice. In modern times, however, the study of death has become a central concern in all these disciplines and in many others.

"So many more people seem to die nowadays," an elderly lady is alleged to have said, scanning the obituary columns of a famous daily. This was not just a comment on the documented passing of a cohort. Various journals now not only list the dead but also describe what they died of, at times in some detail. They openly discuss subjects considered too delicate or personal less than a generation ago. Television interviewers question relatives of the dying—or even the dying themselves—and films depict murders or executions in gruesome and often quite accurate detail. Death is no longer enshrined in taboos. Popular readiness to approach these matters and a general desire to be better informed about them reflect a change in cultural attitudes perhaps as great as that which accompanied the more open discussion of sex after World War I.

Thanatology—the study of death—delves into matters as diverse as the cultural anthropology of the notion of soul, the burial rites and practices of early civilizations, the location of cemeteries in the Middle Ages, and the conceptual difficulties involved in defining death in an individual whose brain is irreversibly dead but whose respiration and heartbeat are kept going by artificial means. It encompasses the biological study of programmed cell death, the understanding care of the dying, and the creation of an informed public opinion as to how the law should cope with the stream of problems generated by intensive-care technology. Legal and medical quandaries regarding the definition of death and the rights of the terminally ill (or their families) to refuse life-prolonging treatments force physicians to think like lawyers, lawyers like physicians, and both like philosophers. In his *Historia Naturalis* (*Natural History*), the Roman author Pliny the Elder wrote that "so uncertain is men's judgment that they cannot determine even death itself." The challenge remains, but if humans now fail to provide some answers it will not be for lack of trying.

This article is divided into the following sections:

THE MEANING OF DEATH

This subject can be approached from a variety of perspectives. It can, for example, be viewed historically, in terms of how popular perceptions of death have been reflected in poetry, literature, legend, or pictorial art. Illustrations of those killed in battle and of their severed parts find particular prominence in ancient Egyptian art. The campaign of the 13th-century-BC Egyptian king Ramses II against the Hittites, in particular the Battle of Kadesh, is recorded in gruesome detail on the battle reliefs of 19th- and 20th-dynasty temples in Upper Egypt. Assyrian art, too, made great play of illustrating cadavers. Those slaughtered by the king Ashurbanipal (flourished 7th century BC) in his campaign against the Arabian king Uate are shown having their eyes plucked out by vultures. These very concrete depictions of the meaning of death seem to have had mainly propagandistic value, boosting the self-confidence of the victors and inspiring fear among the defeated. Deities of the dead were features of many early cultures, but apart from ancient Egypt neither such deities nor those over whom they held dominion were the subject of any significant artistic representation. In Egypt, sepulchral iconography was to reach truly impressive heights, particularly after the democratization of the Osirian cult with its promise of an afterlife for everyone. Well-known sculptors produced some striking individual tombstones in both ancient Greece and Rome, but it was medieval Christianity that gave real impetus to this practice, which can be thought of as an attempt to perpetuate among the living a vivid memory of the dead. The representation of death itself, usually personified in the form of a skeleton, seems to have developed on a large scale only in medieval Christian art.

Artistic representations of the dead

An alternative approach is to look at the meaning of death in terms of various eschatologies (beliefs regarding death and the end of the world). Human beings have been the only species to bury their dead in a systematic way, often with implements to be used in a further existence. The study of death rites and customs illustrates impressively the relation between religious belief and popular practice in the presence of the dead. Such an approach starts from the meaning of death in those cultures (such as Phoenician, early Judaic, Homeric, Epicurean, and Stoic) in which only a shadowy afterlife or no afterlife at all was envisaged; it analyzes other traditions (such as Sumero-Akkadian) in which ambiguities and contradictions abounded; and it finally searches for death's meaning in those cultures (such as ancient Egyptian, Zoroastrian, Hindu, Orphic, Platonic, Christian, Pharisaic Judaic, and Islāmic) in which a very "physical" afterlife, or the presence of an eternal soul, played central roles.

Both the historical and the eschatological approaches share a common advantage: they need not be preceded by a definition of death. They accept death as an easily determined empirical fact, not requiring discussion or further elaboration. But a conceptual crisis has arisen in modern medicine and biology, a crisis that stems precisely from the realization that the definition of death—taken for granted for millennia—requires reexamination. To approach the subject of death from the biological angle, which is perhaps the most difficult and arguably the most challenging perspective, certainly reflects some of the most pressing needs of modern times.

The difficulty of defining death

Many dictionaries define death as "the extinction or cessation of life" or as "ceasing to be." As life itself is notoriously difficult to define—and as everyone tends to think of things in terms of what is known—the problems in defining death are immediately apparent. The most useful definitions of life are those that stress function, whether at the level of physiology, of molecular biology

and biochemistry, or of genetic potential. Death should be thought of as the irreversible loss of such functions.

The remainder of this article first explores the recurrent problems involved in seeking a biological definition of death. It then examines the implications of these problems in relation to human death. In this context, the article raises two major points: (1) death of the brain is the necessary and sufficient condition for death of the individual; and (2) the physiological core of brain death is the death of the brain stem. Finally, the article surveys notions about the meaning of human death that have prevailed throughout history in a wide variety of cultural contexts. By so doing, it attempts to show that brain-stem death, far from being a radically new idea, turns out to have always provided both an ultimate mechanism of death and a satisfactory anatomical basis for a wide range of philosophical concepts relating to death.

THE BIOLOGICAL PROBLEMS

Whether one considers the death of individual cells, the death of small multicellular organisms, or the death of a human being, certain problems are repeatedly met. The physicist may encounter difficulties in trying to define death in terms of entropy change and the second law of thermodynamics. So may the histologist looking at the ultrastructure of dying tissue through an electron microscope. Pope Pius XII, speaking to an International Congress of Anesthesiologists in 1957, raised the question of when, in the intensive care unit, the soul actually left the body. More secularly inclined philosophers have meanwhile pondered what it was that was so essential to the nature of man that its loss should be called death. The questions of what may or may not be legitimately demanded of a "beating-heart cadaver" (in terms of supplying donor organs for transplants or of serving as a subject for physiological experimentation) has given new poignancy to the quip made by the English author Sir Thomas Browne in 1643: "With what strife and pains we come into the world we know not, but 'tis commonly no easy matter to get out of it." Common conceptual difficulties underlie many of these questions.

Death: process or event. The American physician and writer Oliver Wendell Holmes said "to live is to function" and "that is all there is in living." But who or what is the subject who lives because it functions? Is death the irreversible loss of function of the whole organism (or cell); that is, of every one of its component parts? Or is it the irreversible loss of function of the organism (or cell) as a whole; that is, as a meaningful and independent biological unit? To perceive the difference between the two questions is to understand many modern controversies about death. The described dichotomy is clearly part of a much wider one: civilizations fall apart yet their component societies live on; societies disintegrate but their citizens survive; individuals die while their cells, perversely, still metabolize; finally, cells can be disrupted yet the enzymes they release may, for a while, remain active.

Such problems would not arise if nature were tidier. In nearly all circumstances human death is a process rather than an event. Unless caught up in nuclear explosions people do not die suddenly, like the bursting of a bubble.

Death as a process

A quiet, "classical" death provides perhaps the best illustration of death as a process. Several minutes after the heart has stopped beating, a mini-electrocardiogram may be recorded, if one probes for signals from within the cardiac cavity. Three hours later, the pupils still respond to pilocarpine drops by contracting, and muscles repeatedly tapped may still mechanically shorten. A viable skin graft may be obtained from the deceased 24 hours after the heart has stopped, a viable bone graft 48 hours later, and a viable arterial graft as late as 72 hours after the onset of irreversible asystole (cardiac stoppage). Cells clearly differ widely in their ability to withstand the deprivation of oxygen supply that follows arrest of the circulation.

Similar problems arise, but on a vastly larger scale, when the brain is dead but the heart (and other organs) are kept going artificially. Under such circumstances, it can be argued, the organism as a whole may be deemed dead, although the majority of its cells are still alive.

The "point of no return." To claim that death is a process does not imply that this process unfurls at an even rate, or that within it there are not "points of no return." The challenge is to identify such points with greater precision for various biological systems. At the clinical level, the irreversible cessation of circulation has for centuries been considered a point of no return. It has provided (and still provides) a practical and valid criterion of irreversible loss of function of the organism as a whole. What is new is the dawning awareness that circulatory arrest is a mechanism of death and not in itself a philosophical concept of death; that cessation of the heartbeat is only lethal if it lasts long enough to cause critical centres in the brain stem to die; and that this is so because the brain stem is irreplaceable in a way the cardiac pump is not. These are not so much new facts as new ways of looking at old ones.

Failure to establish beyond all doubt that the point of no return had been reached has, throughout the ages, had interesting effects on medical practice. The Thracians, according to the ancient Greek historian Herodotus, kept their dead for three days before burial. The Romans kept the corpse considerably longer; the Roman author Servius, in his commentary on Virgil, records that "on the eighth day they burned the body and on the ninth put its ashes in the grave." The practice of cutting off a finger, to see whether the stump bled, was often resorted to. Even the most eminent proved liable to diagnostic error. The 16th-century Flemish physician Andreas Vesalius, probably the greatest anatomist of all time, professor of surgery in Padua for three years and later physician to the Holy Roman emperor Charles V, had to leave Spain in a hurry in 1564. He was performing a postmortem when the subject, a nobleman he had been attending, showed signs of life. This was at the height of the Spanish Inquisition and Vesalius was pardoned only on the condition that he undertake a pilgrimage to the Holy Sepulchre in Jerusalem.

Anxieties over premature burial

Fears of being buried alive have long haunted humankind. During the 19th century, for example, accounts of "live sepulture" appeared in medical writing and led to repeated demands that putrefaction—the only sure sign of death of the whole organism—be considered an essential prerequisite to a diagnosis of death. Anxieties had become so widespread following the publication of some of U.S. author Edgar Allan Poe's macabre short stories that Count Karnice-Karnicke, a Russian nobleman, patented a coffin of particular type. If the "corpse" regained consciousness after burial, it could summon help from the surface by activating a system of flags and bells. Advertisements described the price of the apparatus as "exceedingly reasonable, only about twelve shillings."

At the turn of the century, a sensation-mongering press alleged that there were "many ugly secrets locked up underground." There may have been some basis for these claims: instances of collapse and apparent death were not uncommon during epidemics of plague, cholera, and smallpox; hospitals and mortuaries were overcrowded, and there was great fear of the spread of infection. This agitation resulted in stricter rules concerning death certification. In the United Kingdom, statutory obligations to register deaths date only from 1874, and at that time it was not even necessary for a doctor to have viewed the corpse.

The impact of medical technology

The second half of the 20th century has seen tremendous developments in the field of intensive care and the emergence of new controversies concerning the point of no return. Modern technology now makes it possible to maintain ventilation (by respirators), cardiac function (by various pumping devices), feeding (by the intravenous route), and the elimination of the waste products of metabolism (by dialysis) in a body whose brain is irreversibly dead. In these macabre by-products of modern technology, a dissociation has taken place between the various components of death so that the most important—the death of the brain—occurs before, rather than after, the cessation of other functions, such as circulation. Such cases have presented both practical and conceptual problems, but the latter need not have arisen had what happens during decapitation been better appreciated.

"Beating-heart cadavers" were of course familiar to the observant long before the days of intensive care units. A

photograph of a public decapitation in a Bangkok square in the mid-1930s illustrates such a case. The victim is tied to a stake and the head has been severed, but jets of blood from the carotid and vertebral arteries in the neck show that the heart is still beating. It is doubtful that anyone would describe the executed man—as distinct from some of his organs—as still alive. This gruesome example stresses three points: it reiterates the fact, admittedly from an unusual angle, that death is a process rather than an event; it emphasizes the fact that in this process there is a point of no return; and it graphically illustrates the difference between the death of the organism as a whole and the death of the whole organism. In thinking the implications through, one takes the first steps toward understanding brain death. The executed man has undergone anatomical decapitation. Brain death is physiological decapitation: it arises when intracranial pressure exceeds arterial pressure, thereby depriving the brain of its blood supply as efficiently as if the head had been cut off. The example serves as an introduction to the proposition that the death of the brain is the necessary and sufficient condition for the death of the individual.

These issues were authoritatively discussed in 1968, at the 22nd World Medical Assembly in Sydney, Australia. The assembly stated that "clinical interest lies not in the state of preservation of isolated cells but in the fate of a person. The point of death of the different cells and organs is not as important as the certainty that the process has become irreversible." The statement had a profound effect on modern medical thinking. "Irreversible loss of function of the organism as a whole" became an accepted clinical criterion of death.

Semantic confusion may underlie some of the controversies outlined in this section. In many languages, including English, the word *death* may be used in various ways. The *Concise Oxford Dictionary* for instance defines death both as "dying" (a process) and as "being dead" (a state). Expressions such as "a painful death" and "a lingering death" show how often the word is used in the former sense. Many people are afraid of dying yet can face the prospect of being dead with equanimity. Another source of confusion that bedevils discussions about death is what the great English mathematician and philosopher Alfred North Whitehead called the "fallacy of misplaced concreteness." This occurs when one treats an abstraction (however useful it may be to denote the behaviour or properties of objects under specific circumstances) as if it were itself a material thing. "O death, where is thy sting?" may be a searching metaphorical question, but such queries can only confuse the biologist. When the poet John Milton wrote of "the pain of death denounced, whatever *thing* death be," the conceptual problem was of his own making.

The next two sections of this article illustrate these general principles concerning death from each end of the spectrum of living things: from the level of the cell and from that of the fully developed human being.

CELL DEATH

A vast amount of work has been devoted since the late 19th century to discovering how cells multiply. The study of how and why they die is a relatively recent concern: a rubric entitled "cell death" only appeared in the *Index Medicus,* an index to medical literature, in 1979.

Cell necrosis

What most textbooks of pathology describe as cell death is coagulative necrosis. This is an abnormal morphological appearance, detected in tissue examined under the microscope. The changes, which affect aggregates of adjacent cells or functionally related cohorts of cells, are seen in a variety of contexts produced by accident, injury, or disease. Among the environmental perturbations that may cause cell necrosis are oxygen deprivation (anoxia), hyperthermia, immunological attack, and exposure to various toxins that inhibit crucial intracellular metabolic processes. Coagulative necrosis is the classical form of cell change seen when tissues autolyze (digest themselves) in vitro.

But cells may die by design as well as by accident. Research in developmental pathology has stressed the biological importance of this other kind of cell death, which has been referred to as programmed cell death. In vertebrates it has been called apoptosis and in invertebrates, cell deletion. Programmed cell death plays an important role in vertebrate ontogeny (embryological development) and teratogenesis (the production of malformations), as well as in the spectacular metamorphoses that affect tadpoles or caterpillars. Such programmed events are essential if the organism as a whole is to develop its normal final form. Waves of genetically driven cell death are critical to the proper modeling of organs and systems. The inflections (curvatures) of the developing mammalian brain and spinal cord, for instance, or the achievement of a proper numerical balance between functionally related cell groups, cannot be understood without an appreciation of how the death of some (or many) cells is necessary for others to reach maturity. Localized cell death, occurring at precise moments during normal ontogeny, explains phenomena as varied as the fashioning of the digits or the involution of phylogenetic vestiges. Several congenital abnormalities can be attributed to disorders of programmed cell death. Cell death occurs spontaneously in normally involuting tissues such as the thymus. It can be initiated or inhibited by a variety of environmental stimuli, both physiological and pathological. Cell death even occurs in some of the cells of untreated malignant tumours, and it is seen during tumour regression induced by X rays or radiomimetic cytotoxic agents. Programmed cell death may also play a part in the process of aging, cells being designed to die after a certain number of mitotic divisions. Groups of cells responsible for the colour of human hair, for instance, may cease to function years before the hair itself loses the capacity to grow: the result is the "uncoloured" white hair of old age.

Programmed cell death

The two types of cell death—imposed from without or programmed from within—have different morphological features. Furthermore, different intracellular mechanisms have been incriminated in their production.

Necrosis is characterized by early swelling of the cytoplasm and of the mitochondria (energy-releasing organelles) within it. Later changes include the appearance of localized densities, possibly related to calcium deposition, in the matrix (ground substance) of the mitochondria. This is followed by the dissolution of other cytoplasmic organelles and the separation of affected cells from their neighbours through shearing of intercellular junctions. Nuclear alterations occur late and are relatively unremarkable. The nucleus swells, becomes darker (pyknosis), and ruptures (karyolysis) at about the same time as does the plasma membrane, the outer envelope of the cell. The basic mechanism of necrosis is thought to be a loss of control over cell volume, related to changes in the permeability of the cell membrane. These changes form the basis of several of the tests used to diagnose a necrotic cell in the laboratory. The affected membrane rapidly loses its ion-pumping capacity, and there are dramatic increases in the intracellular concentrations of sodium and calcium ions. This is followed by osmotic shock and the development of intracellular acidosis. The early injury to the mitochondria has profound repercussions on intracellular oxidative metabolism. The point of no return is reached with irreversible damage to mitochondrial structure and function. Later still, the lysosomes (membranous bags of hydrolytic enzymes found in most cells) rupture, releasing their acid enzymes into the cytoplasm of the cell. All this produces an ionic milieu unsuitable to the survival of the nucleus. Loss of the cell's capacity to synthesize protein is the ultimate proof that it is functionally dead.

Mechanisms of necrosis

Programmed cell death usually affects scattered single cells. Early ultrastructural features are the disintegration of cell junctions and condensations of the cytoplasm. The cells shrivel up instead of swelling. Lumps of chromatin aggregate at the surface of the nucleus. The nuclear membrane develops folds, and the nucleus splits into a number of membrane-bound, ultrastructurally well-preserved fragments, which are shed and promptly taken up by specialized scavenger cells or even by ordinary cells in the neighbourhood. Energy-producing mitochondria are preserved until quite late. The nuclear changes seem to be energy-dependent; they may reflect the fact that genes in the

nucleus are beginning to express themselves in new ways, in response to unknown stimuli. One of these responses seems to be the activation of endogenous endonucleases, enzymes in the cell nucleus that "suicidally" disrupt its cardinal functions.

Time alone will tell whether the distinctions between the two types of cell death are valid or spurious, and whether the concept of apoptosis will gain wide acceptance. Reality will probably turn out to be a great deal more complex. Meanwhile, one should retain, without overemphasis, the twin visions of cell death—one in which death approaches the cell from the outside and the other in which death starts from within the living core of the cell itself.

CLINICAL DEATH

At the opposite end of the spectrum from cell death lies the death of a human being. It is obvious that the problems of defining human death cannot be resolved in purely biological terms, divorced from all ethical or cultural considerations. This is because there will be repercussions (burial, mourning, inheritance, etc.) from any decisions made, and because the decisions themselves will have to be socially acceptable in a way that does not apply to the fate of cells in tissue culture.

Unless death is defined at least in outline, the decision that a person is "dead" cannot be verified by any amount of scientific investigation. Technical data can never answer purely conceptual questions. Earlier in this article it was suggested that the death of the brain was the necessary and sufficient condition for the death of the individual, but the word *death* was not given much content beyond the very general definition of "irreversible loss of function." If one seeks to marry conceptions of death prevalent in the oldest cultures with the most up-to-date observations from intensive care units, one might think of human death as the irreversible loss of the capacity for consciousness combined with the irreversible loss of the capacity to breathe. The anatomical basis for such a concept of human death resides in the loss of brain-stem function.

Human death defined

Functions of the brain stem. The brain stem is the area at the base of the brain that includes the mesencephalon (midbrain), the pons, and the medulla. It contains the respiratory and vasomotor centres, which are responsible, respectively, for breathing and the maintenance of blood pressure. Most importantly, it also contains the ascending reticular activating system, which plays a crucial role in maintaining alertness (*i.e.,* in generating the capacity for consciousness); small, strategically situated lesions in the medial tegmental portions of the midbrain and rostral pons cause permanent coma. All of the motor outputs from the cerebral hemispheres—for example, those that mediate movement or speech—are routed through the brain stem, as are the sympathetic and parasympathetic efferent nerve fibres responsible for the integrated functioning of the organism as a whole. Most sensory inputs also travel through the brain stem. This part of the brain is, in fact, so tightly packed with important structures that small lesions there often have devastating effects. By testing various brain-stem reflexes, moreover, the functions of the brain stem can be assessed clinically with an ease, thoroughness, and degree of detail not possible for any other part of the central nervous system.

Capacity for consciousness

It must be stressed that the capacity for consciousness (an upper brain-stem function) is not the same as the content of consciousness (a function of the cerebral hemispheres); it is, rather, an essential precondition of the latter. If there is no functioning brain stem, there can be no meaningful or integrated activity of the cerebral hemispheres, no cognitive or affective life, no thoughts or feelings, no social interaction with the environment, nothing that might legitimize adding the adjective *sapiens* ("wise") to the noun *Homo* ("man"). The "capacity for consciousness" is perhaps the nearest one can get to giving a biological flavour to the notion of "soul."

The capacity to breathe is also a brain-stem function, and apnea (respiratory paralysis) is a crucial manifestation of a nonfunctioning lower brain stem. Alone, of course, it does not imply death; patients with bulbar poliomyelitis, who may have apnea of brain-stem origin, are clearly not dead. Although irreversible apnea has no strictly philosophical dimension, it is useful to include it in any concept of death. This is because of its obvious relation to cardiac function—if spontaneous breathing is lost the heart cannot long continue to function—and perhaps because of its cultural associations with the "breath of life." These aspects are addressed in the later discussion of how death has been envisaged in various cultures.

Mechanisms of brain-stem death. From as far back as medical records have been kept, it has been known that patients with severe head injuries or massive intracranial hemorrhage often die as a result of apnea: breathing stops before the heart does. In such cases, the pressure in the main (supratentorial) compartment of the skull becomes so great that brain tissue herniates through the tentorial opening, a bony and fibrous ring in the membrane that separates the spaces containing the cerebral hemispheres and the cerebellum. The brain stem runs through this opening, and a pressure cone formed by the herniated brain tissue may dislocate the brain stem downward and cause irreversible damage by squeezing it from each side. An early manifestation of such an event is a disturbance of consciousness; a late feature is permanent apnea. This was previously nature's way out.

Pressure cone formation

With the widespread development of intensive care facilities in the 1950s and '60s, more and more such moribund patients were rushed to specialized units and put on ventilators just before spontaneous breathing ceased. In some cases the effect was dramatic. When a blood clot could be evacuated, the primary brain damage and the pressure cone it had caused might prove reversible. Spontaneous breathing would return. In many cases, however, the massive, structural intracranial pathology was irremediable. The ventilator, which had taken over the functions of the paralyzed respiratory centre, enabled oxygenated blood to be delivered to the heart, which went on beating. Physicians were caught up in a therapeutic dilemma partly of their own making: the heart was pumping blood to a dead brain. Sometimes the intracranial pressure was so high that the blood could not even enter the head. Modern technology was exacting a very high price: the beating-heart cadaver.

Brain-stem death may also arise as an intracranial consequence of extracranial events. The main cause in such cases is circulatory arrest. The usual context is delayed or inadequate cardiopulmonary resuscitation following a heart attack. The intracranial repercussions depend on the duration and severity of impaired blood flow to the head. In the 1930s the British physiologist John Scott Haldane had emphasized that oxygen deprivation "not only stopped the machine, but wrecked the machinery." Circulatory arrest lasting two or three minutes can cause widespread and irreversible damage to the cerebral hemispheres while sparing the brain stem, which is more resistant to anoxia. Such patients remain in a "persistent vegetative state." They breathe and swallow spontaneously, grimace in response to pain, and are clinically and electrophysiologically awake, but they show no behavioral evidence of awareness. Their eyes are episodically open (so that the term *coma* is inappropriate to describe them), but their retained capacity for consciousness is not endowed with any content. Some patients have remained like this for many years. Such patients are not dead, and their prognosis depends in large part on the quality of the care they receive. The discussion of their management occasionally abuts onto controversies about euthanasia and the "right to die." These issues are quite different from that of the "determination of death," and failure to distinguish these matters has been the source of great confusion.

Circulatory arrest

If circulatory arrest lasts for more than a few minutes, the brain stem—including its respiratory centre—will be as severely damaged as the cerebral hemispheres. Both the capacity for consciousness and the capacity to breathe will be irreversibly lost. The individual will then show all the clinical features of a dead brain, even if the heart can be restarted.

Evolution of the concept of brain-stem death. It was against this sort of background that French neurologists, in 1958, described a condition they called *coma dépassé*

(literally, "a state beyond coma"). Their patients all had primary, irremediable, structural brain lesions; were deeply comatose; and were incapable of spontaneous breathing. They had not only lost their ability to react to the external world, but they also could no longer control their own internal environment. They became poikilothermic (*i.e.*, they could not control their body temperature, which varied with that of the environment). They could not control their blood pressure or vary their heart rate in response to appropriate stimuli. They could not even retain body water and would pass great volumes of urine. The organism as a whole had clearly ceased to function. *Coma dépassé* was considered a "frontier state" between life and death. Ventilation was continued in the vast majority of such cases until the heartbeat ceased, usually a few days later.

Criteria for recognizing brain death

In 1968 the Ad Hoc Committee of the Harvard Medical School published a report entitled "A Definition of Irreversible Coma" in *The Journal of the American Medical Association*. This watershed article listed criteria for the recognition of the "brain-death syndrome." It stated that the persistence of a state of apneic coma with no evidence of brain-stem and spinal reflexes and a flat electroencephalogram over a period of 24 hours implied brain death, provided the cause of the coma was known and provided reversible causes of brain dysfunction (such as hypothermia or drug intoxication) had been excluded. The report explicitly identified brain death with death (without seeking to define death) and endorsed the withdrawal of respiratory support in such cases. No evidence was published to legitimize the contention that the coma was irreversible; *i.e.*, that if artificial ventilation was continued no such patient ever recovered consciousness, and that all invariably developed asystole. There was wide medical experience among the members of the committee, however, and its contentions have since been massively validated. Not a single exception has come to light.

The next few years witnessed increasing sophistication in the techniques used to diagnose brain death, none of which, however, surpassed basic clinical assessment. In 1973 two neurosurgeons in Minneapolis, Minn., identified the death of the brain stem as the point of no return in the diagnosis of brain death. In 1976 and 1979, the Conference of Royal Colleges and Faculties of the United Kingdom published important memoranda on the subject. The first described the clinical features of a dead brain stem, the second identified brain-stem death with death. In 1981 in the United States, the President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research published a report ("Defining Death") and a list of guidelines very similar to the British ones. The commission also proposed a model statute, called the Uniform Determination of Death Act, which was subsequently endorsed by the American Medical Association, the American Bar Association, and the National Conference of Commissioners on Uniform State Laws and became law in many states. International opinion and practice has moved along similar lines in accepting the concept of brain-stem death.

Diagnosis of brain-stem death. The diagnosis is not technically difficult. In more and more countries, it is made on purely clinical grounds. The aim of the clinical tests is not to probe every neuron within the intracranial cavity to see if it is dead—an impossible task—but to establish irreversible loss of brain-stem function. This is the necessary and sufficient condition for irreversible unconsciousness and irreversible apnea, which together spell a dead patient. Experience has shown that instrumental procedures (such as electroencephalography and studies of cerebral blood flow) that seek to establish widespread loss of cortical function contribute nothing of relevance concerning the cardiac prognosis. Such tests yield answers of dubious reliability to what are widely felt to be the wrong questions. As the concept of brain-stem death is relatively new, most countries rightly insist that the relevant examinations be carried out by physicians of appropriate seniority. These doctors (usually neurologists, anesthetists, or specialists in intensive care) must be entirely separate from any who might be involved in using the patient's organs for subsequent transplants.

Stages in diagnosing brain-stem death

The diagnosis of brain-stem death involves three stages. First, the cause of the coma must be ascertained, and it must be established that the patient (who will always have been in apneic coma and on a ventilator for several hours) is suffering from irremediable, structural brain damage. Damage is judged "irremediable" based on its context, the passage of time, and the failure of all attempts to remedy it. Second, all possible causes of reversible brain-stem dysfunction, such as hypothermia, drug intoxication, or severe metabolic upset, must be excluded. Finally, the absence of all brain-stem reflexes must be demonstrated, and the fact that the patient cannot breathe, however strong the stimulus, must be confirmed.

It may take up to 48 hours to establish that the preconditions and exclusions have been met; the testing of brain-stem function takes less than half an hour. When testing the brain-stem reflexes, doctors check for the following normal responses: (1) constriction of the pupils in response to light, (2) blinking in response to stimulation of the cornea, (3) grimacing in response to firm pressure applied just above the eye socket, (4) movements of the eyes in response to the ears being flushed with ice water, and (5) coughing or gagging in response to a suction catheter being passed down the airway. All responses have to be absent on at least two occasions. Apnea, which also must be confirmed twice, is assessed by disconnecting the patient from the ventilator. (Prior to this test, the patient is fully oxygenated by being made to breathe 100 percent oxygen for several minutes, and diffusion oxygenation into the trachea is maintained throughout the procedure. These precautions ensure that the patient will not suffer serious oxygen deprivation while disconnected from the ventilator.) The purpose of this test is to establish the total absence of any inspiratory effort as the carbon dioxide concentration in the blood (the normal stimulus to breathing) reaches levels more than sufficient to drive any respiratory centre cells that may still be alive.

Tests of brain-stem reflexes

The patient thus passes through a tight double filter of preconditions and exclusions before he is even tested for the presence of a dead brain stem. This emphasis on strict preconditions and exclusions has been a major contribution to the subject of brain-stem death, and it has obviated the need for ancillary investigations. Thousands of patients who have met criteria of this kind have had ventilation maintained: all have developed asystole within a few hours or a few days, and none has ever regained consciousness. There have been no exceptions. The relevant tests for brain-stem death are carried out systematically and without haste. There is no pressure from the transplant team.

The developments in the idea and diagnosis of brain-stem death came as a response to a conceptual challenge. Intensive-care technology had saved many lives, but it had also created many brain-dead patients. To grasp the implications of this situation, society in general—and the medical profession in particular—was forced to rethink accepted notions about death itself. The emphasis had to shift from the most common mechanism of death (*i.e.*, irreversible cessation of the circulation) to the results that ensued when that mechanism came into operation: irreversible loss of the capacity for consciousness, combined with irreversible apnea. These results, which can also be produced by primary intracranial catastrophes, provide philosophically sound, ethically acceptable, and clinically applicable secular equivalents to the concepts of "departure of the soul" and "loss of the 'breath of life,' " which were so important to some earlier cultures.

THE CULTURAL BACKGROUND

Throughout history, specific cultural contexts have always played a crucial role in how people perceived death. Different societies have held widely diverging views on the "breath of life" and on "how the soul left the body" at the time of death. Such ideas are worth reviewing (1) because of the light they throw on important residual elements of popular belief; (2) because they illustrate the distance traveled (or not traveled) between early beliefs and current ones; and (3) because of the relevance of certain old ideas to contemporary debates about brain-stem death and about the philosophical legitimacy of organ transplanta-

tion. The following discussion therefore focuses on how certain cultural ideas about death compare or contrast with the modern concept. For an overview of various eschatologies from a cross-cultural perspective, see RITES AND CEREMONIES, SACRED: *Death rites and customs.*

Ancient Egypt. Two ideas that prevailed in ancient Egypt came to exert great influence on the concept of death in other cultures. The first was the notion, epitomized in the Osirian myth, of a dying and rising saviour god who could confer on devotees the gift of immortality; this afterlife was first sought by the pharaohs and then by millions of ordinary people. The second was the concept of a postmortem judgment, in which the quality of the deceased's life would influence his ultimate fate. Egyptian society, it has been said, consisted of the dead, the gods, and the living. During all periods of their history, the ancient Egyptians seem to have spent much of their time thinking of death and making provisions for their afterlife. The vast size, awe-inspiring character, and the ubiquity of their funerary monuments bear testimony to this obsession.

The physical preservation of the body was central to all concerns about an afterlife; the Egyptians were a practical people, and the notion of a disembodied existence would have been totally unacceptable to them. The components of the person were viewed as many, subtle, and complex; moreover, they were thought to suffer different fates at the time of death. The physical body was a person's *khat,* a term that implied inherent decay. The *ka* was the individual's doppelgänger, or double; it was endowed with all the person's qualities and faults. It is uncertain where the *ka* resided during life, but "to go to one's *ka*" was a euphemism for death. The *ka* denoted power and prosperity. After death it could eat, drink, and "enjoy the odour of incense." It had to be fed, and this task was to devolve on a specific group of priests. The *ka* gave comfort and protection to the deceased: its hieroglyphic sign showed two arms outstretched upward, in an attitude of embrace.

The *ba*

The *ba* (often translated as "the soul") conveyed notions of "the noble" and "the sublime." It could enter the body or become incorporeal at will. It was represented as a human-headed falcon, presumably to emphasize its mobility. The *ba* remained sentimentally attached to the dead body, for whose well-being it was somehow responsible. It is often depicted flying about the portal of the tomb or perched on a nearby tree. Although its anatomical substratum was ill-defined, it could not survive without the preserved body.

Other important attributes were an individual's *khu* ("spiritual intelligence"), *sekhem* ("power"), *khaibit* ("shadow"), and *ren* ("name"). In the pyramid of King Pepi I, who ruled during the 6th dynasty (*c.* 2345–*c.* 2182 BC), it is recorded how the dead king had "walked through the iron which is the ceiling of heaven. With his panther skin upon him, Pepi passeth with his flesh, he is happy with his name, and he liveth with his double." The depictions of the dead were blueprints for immortality. Conversely, to blot out a person's name was to destroy that individual for all eternity, to eliminate him from the historical record. The Stalinist and Maoist regimes in the Soviet Union and China were later to resort to the same means, with the same end in mind. They also, however, invented the concept of "posthumous rehabilitation."

The heart played a central part in how the Egyptians thought about the functioning of the body. Political and religious considerations probably lay behind the major role attributed to the heart. Many of the so-called facts reported in the Ebers papyrus (a kind of medical encyclopaedia dating from the early part of the 18th dynasty; *i.e.,* from about 1550 BC) are really just speculations. This is surprising in view of how often bodies were opened during embalmment. A tubular system was rightly said to go from the heart "to all members" and the heart was said "to speak out of the vessels of every limb." But the vessels were thought to convey a mixture of air, blood, tears, urine, saliva, nasal mucus, semen, and at times even feces. During the process of embalming, the heart was always left in situ or replaced in the thorax. According to the renowned Orientalist Sir Wallis Budge, the Egyptians saw the heart as the "source of life and being," and any damage to it would have resulted in a "second death" in which everything (*ka, ba, khu,* and *ren*) would be destroyed. In some sarcophagi one can still read the pathetic plea "spare us a second death."

The anatomical heart was the *haty,* the word *ib* referring to the heart as a metaphysical entity embodying not only thought, intelligence, memory, and wisdom, but also bravery, sadness, and love. It was the heart in its sense of *ib* that was weighed in the famous judgment scene depicted in the Ani papyrus and elsewhere. After the deceased had enumerated the many sins he had not committed (the so-called negative confession), the heart was weighed against the feather of Ma'at (*i.e.,* against what was deemed right and true). It had to prove itself capable of achieving balance with the symbol of the law. The deceased who was judged pure was introduced to Osiris (in fact, became an Osiris). The deceased who failed was devoured by the monster Am-mit, the "eater of the dead." It was never the physical body on earth that was resurrected, but a new entity (the *Sahu*) that "germinated" from it and into which the soul would slip.

Judgment of the dead

The Egyptians were concerned that the dead should be able to breathe again. The Pyramid Texts describe the ceremony of the "opening of the mouth," by which this was achieved. Immediately before the mummy was consigned to the sepulchral chamber, specially qualified priests placed it upright, touched the face with an adz, and proclaimed "thy mouth is opened by Horus with his little finger, with which he also opened the mouth of his father Osiris." It has proved difficult to relate this ritual, in any meaningful way, to specific beliefs about the *ka* or *ba.*

The brain is not mentioned much in any of the extant medical papyruses from ancient Egypt. It is occasionally described as an organ producing mucus, which drained out through the nose; or it is referred to by a generic term applicable to the viscera as a whole. Life and death were matters of the heart, although the suggested relationships were at times bizarre—for example, it was said that the "mind passed away" when the vessels of the heart were contaminated with feces. The only reference that might relate death to the brain stem is the strange statement in the Ebers papyrus (gloss 854f) to the effect that "life entered the body through the left ear, and departed through the right one."

It is clear why the Egyptians never cremated their dead: to do so would have destroyed for the deceased all prospects of an afterlife. Fortunately, there was no question of organ transplantation; in the prevailing cultural context, it would never have been tolerated. Whether the pharaohs would have been powerful enough—or rash enough—to transgress accepted norms had transplantation been feasible is quite another matter.

Mesopotamia. The Mesopotamian (Sumerian, Babylonian, and Assyrian) attitudes to death differed widely from those of the Egyptians. They were grim and stark: sickness and death were the wages of sin. This view was to percolate, with pitiless logic and simplicity, through Judaism into Christianity. Although the dead were buried in Mesopotamia, no attempts were made to preserve their bodies.

According to Mesopotamian mythology, the gods had made humans of clay, but to the clay had been added the flesh and blood of a god specially slaughtered for the occasion. God was, therefore, present in all people. The sole purpose of humanity's creation was to serve the gods, to carry the yoke and labour for them. Offended gods withdrew their support, thereby opening the door to demons, whose activities the malevolent could invoke.

Notions of the afterlife

The main strands of Sumero-Akkadian thought held no prospect of an afterlife, at any rate of a kind that anyone might look forward to. In the Gilgamesh epic, the aging folk hero, haunted by the prospect of his own death, sets off to visit Utnapishtim, who, with his wife, was the only mortal to have achieved immortality. He meets Siduri, the wine maiden, who exhorts him to make the most of the present for "the life which thou seekest thou wilt not find." There was no judgment after death, a common fate awaiting the good and the bad alike. Death was conceived

of in terms of appalling grimness, unrelieved by any hope of salvation through human effort or divine compassion. The dead were, in fact, among the most dreaded beings in early Mesopotamian demonology. In a myth called "The Descent of Ishtar to the Underworld," the fertility goddess decides to visit *kur-nu-gi-a* ("the land of no return"), where the dead "live in darkness, eat clay, and are clothed like birds with wings." She threatens the doorkeeper: "If thou openest not that I may enter I will smash the doorpost and unhinge the gate. I will lead up the dead, that they may eat the living." Given this background, it is not surprising that offerings to the dead were made in a spirit of fear; if not propitiated they would return and cause all kinds of damage.

The Babylonians did not dissect bodies, and their approach to disease and death was spiritual rather than anatomical or physiological. They did not speculate about the functions of organs but considered them the seat of emotions and mental faculties in general. The heart was believed to be the seat of the intellect, the liver of affectivity, the stomach of cunning, the uterus of compassion, and the ears and the eyes of attention. Breathing and life were thought of in the same terms. The Akkadian word *napistu* was used indifferently to mean "the throat," "to breathe," and "life" itself.

Judaism. The canonical writings of biblical Judaism record the relations between certain outstanding individuals and their god. The events described are perceived as landmarks in the unfurling of a national destiny, designed and guided by that god. Jewish eschatology is in this sense unique: its main concern is the fate of a nation, not what happens to an individual at death or thereafter.

Absence of an afterlife in classical Judaism

In classical Judaism death closes the book. As the anonymous author of Ecclesiastes bluntly put it: "For the living know that they will die, but the dead know nothing, and they have no more reward" (Eccles. 9:5). The death of human beings was like that of animals: "As one dies, so dies the other. They all have the same breath, and man has no advantage over the beasts . . . all are from the dust, and all turn to dust again" (Eccles. 3:19–20). Life alone mattered: "A living dog is better than a dead lion" (Eccles. 9:4). Even Job, whose questioning at times verges on subverting Yahwist doctrine, ends up endorsing the official creed: "Man dies, and is laid low . . . . As waters fail from a lake, and a river wastes away and dries up, So man lies down and rises not again; till the heavens are no more he will not awake, or be roused out of his sleep" (Job 14:10–12).

Yet such views were far from universal. The archaeological record suggests that the various racial elements assimilated to form the Jewish nation each had brought to the new community its own tribal customs, often based on beliefs in an afterlife. Both Moses (Deut. 14:1) and Jeremiah (Jer. 16:6) denounced mortuary practices taken to imply such beliefs. Necromancy, although officially forbidden, was widely practiced, even in high places. Saul's request to the witch of Endor to "bring up" the dead prophet Samuel for him (I Sam. 28:3–20) implied that the dead, or at least some of them, still existed somewhere or other, probably in Sheol, "the land of gloom and deep darkness" (Job 10:21). In Sheol, the good and the wicked shared a common fate, much as they had in the Babylonian underworld. The place did not conjure up images of an afterlife, for nothing happened there. It was literally inconceivable, and this is what made it frightening: death was utterly definitive, even if rather ill-defined.

Many were unsatisfied by the idea that individual lives only had meaning inasmuch as they influenced the nation's destiny for good or ill. There was only one life, they were told, yet their everyday experience challenged the view that it was on earth that Yahweh rewarded the pious and punished the wicked. The Book of Job offered little solace: it was irrelevant that the good suffered and that the wicked prospered. One did not pray to improve one's prospects. The worship of God was an end in itself; it was what gave meaning to life. Against this backdrop of beliefs, the longing for personal significance was widespread.

It is difficult to determine when the notion of soul first emerged in Jewish writings. The problem is partly philological. The word *nefesh* originally meant "neck" or "throat," and later came to imply the "vital spirit," or *anima* in the Latin sense. The word *ruach* had at all times meant "wind" but later came to refer to the whole range of a person's emotional, intellectual, and volitional life. It even designated ghosts. Both terms were widely used and conveyed a wide variety of meanings at different times, and both were often translated as "soul."

The notion of a resurrection of the dead has a more concrete evolution. It seems to have originated during Judaism's Hellenistic period (4th century BC–2nd century AD). Isaiah announced that the "dead shall live, their bodies shall rise," and the "dwellers in the dust" would be enjoined to "awake and sing" (Isa. 26:19). Both the good and the wicked would be resurrected. According to their deserts, some would be granted "everlasting life," others consigned to an existence of "shame and everlasting contempt" (Dan. 12:2). The idea that a person's future would be determined by conduct on earth was to have profound repercussions. The first beneficiaries seem to have been those killed in battle on behalf of Israel. Judas Maccabeus, the 2nd-century-BC Jewish patriot who led a struggle against Seleucid domination and Greek cultural penetration, found that his own supporters had infringed the law. He collected money and sent it to Jerusalem to expiate their sins, acting thereby "very well and honorably, taking account of the resurrection. For if he were not expecting that those who had fallen would rise again, it would have been superfluous and foolish to pray for the dead" (II Macc. 12:43–45).

Emerging ideas of an afterlife

Sheol itself became departmentalized. According to the *First Book of Enoch,* a noncanonical work believed to have been written between the 2nd century BC and the 2nd century AD, Sheol was composed of three divisions, to which the dead would be assigned according to their moral deserts. The real Ge Hinnom ("Valley of Hinnom"), where the early Israelites were said to have sacrificed their children to Moloch (and in which later biblical generations incinerated Jerusalem's municipal rubbish), was transmuted into the notion of Gehenna, a vast camp designed for torturing the wicked by fire. This was a clear precursor of things to come—the Christian and Islāmic versions of hell.

Orphic and Platonic ideas also came to exert a profound influence on the Judaic concept of death. These were perhaps expressed most clearly in the apocryphal text known as the Wisdom of Solomon, written during the 1st century BC and reflecting the views of a cultured Jew of the Diaspora. The author stressed that a "perishable body weighs down the soul" (Wisd. Sol. 9:15) and stated that "being good" he had "entered an undefiled body" (Wisd. Sol. 8:20), a viewpoint that was quintessentially Platonic in its vision of a soul that predated the body. Flavius Josephus, the Jewish historian of the 1st century AD, recorded in *Bellum Judaicum* (*History of the Jewish War*) how doctrinal disputes about death, the existence of an afterlife, and the "fate of the soul" were embodied in the views of various factions. The Sadducees (who spoke for a conservative, sacerdotal aristocracy) were still talking in terms of the old Yahwist doctrines, while the Pharisees (who reflected the views of a more liberal middle class) spoke of immortal souls, some doomed to eternal torment, others promised passage into another body). The Essenes held views close to those of the early Christians.

Following the destruction of the Temple (AD 70) and, more particularly, after the collapse of the last resistance to the Romans (*c.* 135), rabbinic teaching and exegesis slowly got under way. These flowered under Judah ha-Nasi ("Judah the Prince"), who, during his reign (*c.* 175–*c.* 220) as patriarch of the Jewish community in Palestine, compiled the collection of rabbinic law known as the Mishna. During the next 400 years or so, rabbinic teaching flourished, resulting in the production and repeated reelaboration first of the Palestinian (Jerusalem) and then of the Babylonian Talmuds. These codes of civil and religious practice sought to determine every aspect of life, including attitudes toward the dead. The concepts of immortality and resurrection had become so well established that in the Eighteen Benedictions (recited daily in syna-

Rabbinic teachings on immortality

gogues and homes) God was repeatedly addressed as "the One who resurrects the dead." Talmudic sources warned that "anyone who said there was no resurrection" would have no share in the world to come (tractate *Sanhedrin* 10:1). Over the centuries, a radical doctrinal shift had occurred. One would have to await the great political volte-faces of the 20th century to witness again such dramatic gyrations of decreed perspective.

One of the strangest notions to be advanced by rabbinic Judaism—and of relevance to the evolution of the concept of death—was that of the "bone called Luz" (or *Judenknöchlein,* as it was to be called by early German anatomists). In his *Glossa magna in Pentateuchum* (AD 210), Rabbi Oshaia had affirmed that there was a bone in the human body, just below the 18th vertebra, that never died. It could not be destroyed by fire, water, or any other element, nor could it be broken or bruised by any force. In his exceeding wisdom, God would use this bone in the act of resurrection, other bones coalescing with it to form the new body that, duly breathed upon by the divine spirit, would be raised from the dead. The name of the bone was derived from *lus,* an old Aramaic word meaning "almond." The emperor Hadrian had apparently once asked Rabbi Joshua, son of Chanin, how God would resurrect people in the world to come. The rabbi had answered "from the bone Luz in the spinal column." He had then produced a specimen of such a bone, which could not be softened in water or destroyed by fire. When struck with a hammer, the bone had remained intact while the anvil upon which it lay had been shattered. The bone had apparently been called Aldabaran by the Arabs. In some of the most interesting writings of polemical anatomy, Vesalius showed, in 1543, that the bone did not exist.

Orthodox responses to the beating-heart cadaver

Orthodox Jewish responses to current medical controversies concerning death are based on biblical and Talmudic ethical imperatives. First, nothing must be done that might conceivably hasten death. Life being of infinite worth, a few seconds of it are likewise infinitely valuable. Causing accidental death is seen as only one step removed from murder. When a patient is in the pangs of death the bed should not be shaken, as even this might prove to be the last straw. Such invasive diagnostic procedures as four-vessel angiography (to assess cerebral blood flow) would almost certainly be frowned upon. Even a venipuncture (say, for tissue typing) could be conceived of as *shpikhut damim,* a spilling of blood with nefarious intent. In secular medical practice, however, problems of this sort are unlikely to arise. Much more important is the conceptual challenge presented by the beating-heart cadaver. Here it must be stressed that absence of a heartbeat was never considered a cardinal factor in the determination of death (Bab. Talmud, tractate *Yoma* 85A). Talmudic texts, moreover, clearly recognized that death was a process and not an event: "the death throes of a decapitated man are not signs of life any more than are the twitchings of a lizard's amputated tail" (Bab. Talmud, tractate *Chullin* 21A; Mishna, *Oholoth* 1:6). The decapitated state itself defined death (Maimonides: *Tumath Meth* 1:15). Brain-stem death, which is physiological decapitation, can readily be equated with death in this particular perspective.

What mattered, in early Jewish sources, was the capacity to breathe spontaneously, which was seen as an indicator of the living state. The Babylonian Talmud (tractate *Yoma* 85A) explained that when a building collapsed, all life-saving activities could legitimately cease on determination that the victim was no longer breathing. The instructions were quite explicit: "As soon as the nose is uncovered no further examination need be made, for the Tanach (Bible) refers to 'all living things who have the breath of life in their nostrils.' "

Apnea alone, of course, does not constitute death; it is a necessary but not a sufficient condition for such a diagnosis. But if apnea is conjoined to all that is implied in the notion of the decapitated state (in terms of the irreversible loss of the capacity for consciousness, for instance), one finds that the concepts of death in the Talmud and in the most modern intensive care unit are virtually identical.

The issue of transplantation is more complex. The Talmud forbids the mutilation of a corpse or the deriving of any benefit from a dead body, but these considerations can be overridden by the prescriptions of *pikuakh nefesh* ("the preservation of life"). The Chief Rabbi of Israel has even argued that, as a successful graft ultimately becomes part of the recipient, prohibitions related to deriving benefit from the dead do not, in the long run, apply.

Hinduism. Among the collected hymns of the Rigveda (which may date from 1500 BC and probably constitute the earliest known book in the world), there is a "Song of Creation." "Death was not there," it states, "nor was there aught immortal." The world was a total void, except for "one thing, breathless, yet breathed by its own nature." This is the first recorded insight into the importance of respiration to potential life.

Later, by about 600 BC, the *Upaniṣad*s (a collection of searching, intellectually stimulating Indo-Aryan texts) record the quest for a coordinating principle that might underlie such diverse functions of the individual as speech, hearing, and intellect. An essential attribute of the living was their ability to breathe (*an*). Their *praṇa* ("breath") was so vital that on its cessation the body and its faculties became lifeless and still. The word for "soul," *ātman,* is derived from *an,* thus placing the concept of breath at the very core of the individual self or soul.

The Hindu concept of the soul is central to an understanding of most Hindu practices related to death. In *The Discovery of India,* Jawaharlal Nehru described Hinduism as a faith that was "vague, amorphous, many-sided and all things to all men." The practices that the religion inspires do indeed entail acts that appear contradictory. What is unique to Hinduism, however, is that these are not perceived as contradictions. A common thread unites the most abstract philosophical speculations and childish beliefs in ghosts; a deep respect for nonviolence and the bloodiness of certain sacrificial rites; extreme asceticism and the sexual aspects of Tantric worship. At very different levels of sophistication, these all represent attempts to expand human perception of the truth and to achieve a cosmic consciousness. To the intellectually inclined Hindu, the eternal, infinite, and all-pervasive principle of Brahman alone is real, and the acquisition of cosmic consciousness allows humans to become one with it. The individual soul (*ātman*) is merely a particle of this cosmic principle, the relationship being likened to that between air, temporarily trapped in an earthen jar, and the endless space without; or to that between a particular wave and the ocean as a whole.

The cycle of rebirths

Death practices are probably more important in Hinduism than in any other religion. At one level they derive from explicit religious premises. Each being is predestined to innumerable rebirths (*saṃsāra*), and one's aggregate moral balance sheet (*karman*) determines both the length of each life and the specific form of each rebirth. Moral attributes are minutely quantifiable causal agents: every grain sown in this existence is reaped in the next. The prospect of innumerable lives is therefore envisaged with dismay. To escape the dreaded rebirths is to achieve final emancipation (*mokṣa*). "Life everlasting" (at least of the type already sampled) is the last thing a Hindu would aspire to. *Mokṣa* can be achieved only by the saintly, or perhaps by those who have died in Vārānasi and had their ashes strewed on the Ganges River. For others, the wages of worldliness is inevitable reincarnation.

Hindu death practices, however, also reflect popular beliefs and fears, as well as local customs. They thus may vary considerably from region to region or from sect to sect, bearing a rather variable relation to religious doctrine. Many practices are derived from the *Dharma-śastra* of Manu, the most authoritative of the books of Hindu sacred law. The alleged author of the book is the mythical sage Manu, who combined flood-surviving attributes (like Noah of Jews and Christians, and Utnapishtim of the Mesopotamians) with law-giving propensities (like Moses and Hammurabi). The book, which grew by repeated additions over many centuries, reflects the evolving interests of a male Brahman priesthood: its prescriptions are overwhelmingly recorded in terms of what is appropriate for men. Women are seldom referred to, and then often in derogatory terms.

Death practices. Hindus hold that a span of 120 years has been allotted to human life, a strange notion in a country where the average life expectancy was under 30 into the 20th century. They have no difficulty with the concept of death as a process. Mythological beliefs involving early Vedic gods held that the god reigning over the ears departed early, as did the gods of the eyes, hands, and mind.

When devout Hindus sense death approaching, they begin repeating the monosyllable *Om*. (This word refers to Brahman and is widely used in religious observance to help concentrate the mind on what matters.) If it is the last word on a person's lips, it guarantees a direct passage to *mokṣa*. When the dying are judged to have only an hour or so left, they are moved from their bed to a mattress on the floor and their heads are shaved. The space between ground and the ceiling is thought to symbolize the troubled area between earth and sky, and those dying there may return after death as evil spirits. A space on the ground is sanctified with Ganges water and various other ingredients, including cow dung, barley, and sesame seeds. A Hindu should never die in bed, but lying on the ground. As they take their last breaths, the dying are moved from the mattress to ground. Experienced members of the family are usually present to help decide the opportune moment. Water taken from the confluence of the rivers Ganges and Yamuna (at Allahābād) is poured into the mouth, into which is also placed a leaf of the tulsi plant (*Ocimum sanctum*). The forehead is smeared with white clay (*gopi candana*). A woman whose death precedes her husband's is considered so fortunate that her face, and especially her forehead, may be smeared with red. Sometimes, if there is doubt as to whether death has occurred, a lump of ghee (clarified butter) is placed on the forehead; if it does not melt, it is taken as a sign that life is extinct—an interesting but potentially misleading practice in the light of modern awareness of how hypothermia can mimic death. The dead body is wrapped in clean cloth of varying colours that indicate age. In the home the relatives walk clockwise around the body; they will walk around the funeral pyre in the opposite direction.

Rituals for the dying

The body is looked upon as an offering to Agni, god of fire. According to the Vedas, the Indo-Aryans used to bury their dead. Why the Hindus and Buddhists burn theirs has been the subject of much controversy. It has been variously interpreted as a gesture of purification, as the most efficient means of releasing the soul from the corrupted body, as a public health measure with important ecological benefits in a crowded country, or as a symbol of the transitory nature of any particular life and the desire that it should end in permanent anonymity. Fire taken from the deceased's home is transported to the cremation ground in a black earthen pot; this is carried immediately in front of the deceased, and nothing must come between them. For many years women were not allowed to follow the cortege, and only the wives of Brahmans could walk around the pyre. At the cremation site, a lighted torch is handed to the eldest son or grandson, who ignites the pyre, near the feet of the dead woman, at the head of the dead man. While the body is burning the soul is thought to seek refuge within the head. The intense heat usually explodes the skull, liberating the soul; when this does not happen spontaneously, the skull is deliberately shattered by blows from a cudgel. Other traditions hold that the soul passes out through the nose, eyes, and mouth. Some believe it is better still if it leaves through the anterior fontanel, an opening in the skull that normally closes during early childhood. Such theorists hold that if the deceased has practiced yoga or intense meditation, this opening will reopen, allowing free passage to the soul. In some parts of India it is believed that the souls of the really wicked depart through the rectum, and in so doing acquire such defilement that endless purification is necessary.

Cremation

Children under the age of two are not cremated but buried. When dying, they are not placed on the ground; instead they are allowed to expire in their mothers' arms. There are no special death rites; it is felt the child must have been a monster of iniquity in its previous life to have incurred such a terrible *karman*. Infant mortality is clearly attributed to the child's own wickedness and carries a load of 84 *lakh*s of rebirths (*i.e.*, the child has to be reborn 8,400,000 times). The ceremonial defilement of relatives is short, lasting only three days. Among the very high-caste Nagaras, when a pregnant woman dies the fetus is removed and buried, while the mother is cremated.

Ascetics, too, are buried rather than burnt, usually in an upright posture with the body surrounded with salt. Lepers and smallpox victims used to be buried in a recumbent position. Smallpox has been eradicated, and leprosy victims are usually cremated. If a Hindu "breaks caste" by becoming either a Muslim or a Christian, a death ceremony is conducted, the relatives bathe to purge their defilement, and the person's name is never mentioned again. The concept of death clearly influences what is deemed appropriate death behaviour, as was argued earlier in this article.

The fate of the soul. What happens between death and reincarnation is seldom discussed in articles about Hinduism. This is regrettable, for the perception of these events helps explain some of the rites of the religion and provides unique insights into the human preference, when thinking about death, to conceptualize metaphysical developments in very concrete terms.

Immediately after death, the soul is not clothed in a physical body but in a vaporous thumb-sized structure (*linga śarīra*). This is immediately seized by two servants of Yama, the god of death, who carry it to their master for a preliminary identity check. Afterward, the soul is promptly returned to the abode of the deceased, where it hovers around the doorstep. It is important that the cremation be completed by the time of the soul's return, to prevent it from reentering the body. By the 10th day, the near relatives have purged some of the defilement (*mṛitaka sutaka*) they incurred from the death, and the chief mourner and a priest are ready to carry out the first *śrāddha* (ritual of respect). This is a step toward the reconstitution of a more substantial physical body (*yatana śarīra*) around the disembodied soul (*preta*) of the deceased. A tiny trench is dug in a ritually purified piece of land by a river, and the presence of Vishnu is invoked. Ten balls of barley flour mixed with sugar, honey, milk, curds, ghee, and sesame seeds are then placed, one by one, in the soil. As the first ball is offered, the priest says (and the son repeats after him), "May this create a head"; with the second ball, "May this create neck and shoulders"; with the third, "May this create heart and chest"; and so on. The 10th request is for the ball to create the capacity to digest, thereby satisfying the hunger and thirst of the newly created body. Bungled ceremonies can have catastrophic effects. Prayers are offered to Vishnu to help deliver the new entity (now perceived as some 18 inches [46 centimetres] long) into the power of Yama. The balls of barley are picked up from the trench and thrown into the river. Further *śrāddha*s are performed at prescribed times, varying according to caste; one of these rituals makes the soul an ancestral spirit, or *pitṛi*. With the completion of these rituals, the soul of the deceased leaves this world for its yearlong and perilous journey to Yama's kingdom. The family is now formally cleansed. The men shave their heads, and the women wash their hair. The family's tutelary god (removed by a friend at the time of the death) can be returned to its home. A feast is offered to Brahmans, neighbours, and beggars—even the local cows are given fresh grass. There is a sense of general relief: if the *śrāddha*s had not been performed, the *preta* could have become a *bhūta* (malignant spirit), repeatedly turning up to frighten the living. For the deceased, things would have been worse: the *preta* would have been left errant. (A similar fate befalls the soul of a person who commits suicide.) The horror of dying unshriven that haunted people in medieval Europe resembles the despair of the devout Hindu at the prospect of having no son to perform the *śrāddha*s.

The first *śrāddha*

The soul, in its substantial envelope, is meanwhile proceeding on its journey, holding onto a cow's tail to cross the Vaitarani, a horrible river of blood and filth that marks the boundary of Yama's kingdom. Throughout, it is sustained by further *śrāddha*s, during which friends on

Later rituals

earth seek to provide it with shoes, umbrellas, clothing, and money. These they give to a Brahman, in the hope that the deceased will benefit. During such rituals relatives have to avoid all sewing, which might occlude the *pitṛī*'s throat, rendering it incapable of ever breathing or drinking again. After a year, the *pitṛi* in its *yatana śarīra* reaches Yama's seat of judgment, where it is sentenced to a strictly limited term in heaven (*svarga*) or hell (*naraka*) according to its deserts. This completed, it moves into another body (the *karaṇa śarīra*), whose form depends on the individual's *karman*. It could be a plant, a cockroach, a canine intestinal parasite, a mouse, or a human being. Unlike Jains, Hindus believe that whatever body the soul eventually moves into, it inhabits as sole tenant, not as a tenement lodger.

Islām. Probably no religion deals in such graphic detail as does Islām with the creation, death, "life in the tomb," and ultimate fate of humankind. Yet the Qur'ān, the holy book of Islām, itself provides no uniform or systematic approach to these problems. It is only in its later parts (which date from the period when the small Muslim community in Medina had come into contact with other religious influences) that problems such as the relation of sleep to death, the significance of breathing, and the question of when and how the soul leaves the body are addressed in any detail. Popular Muslim beliefs are based on still later traditions. These are recorded in the *Kitāb al-rūḥ* ("Book of the Soul") written in the 14th century by the Ḥanbalī theologian Muḥammad ibn Abī-Bakr ibn Qayyīm al-Jawzīyah.

Predestination in Islāmic teachings

The basic premise of all Qur'ānic teaching concerning death is Allāh's omnipotence: he creates human beings, determines their life span, and causes them to die. The Qur'ān states: "Some will die early, while others are made to live to a miserable old age, when all that they once knew they shall know no more (22:5; *i.e., sūrah* [chapter] 22, verse 5). Damnation and salvation are equally predetermined: "Allāh leaves to stray whom he willeth, and guideth whom he willeth" (35:8). As for those whom Allāh leaves astray, the Qur'ān states that "for them there will be no helpers" (30:29). Allāh has decided many will fail: "If We had so willed We could certainly cause proper guidance to come to every soul, but true is My saying 'assuredly I shall fill Jihannam' " (32:13).

In this perspective the individual's fate (including the mode and time of death) appears inescapably predetermined. The very term *Islām,* Arabic for "surrender," implies an absolute submission to the will of God. But what freedom does this allow those predestined to continue in the path of error, or to reject God's will? And if there is no such freedom, what sense was there in the mission of the Prophet Muḥammad (Islām's founder) and his appeal to people to alter their ways? It is hardly surprising that arguments about free will and predestination broke out soon after the Prophet's death. The ensuing tensions dominated theological (and other) controversies within Islām during many centuries.

Questions concerning the meaning of life and the nature of the soul are dealt with patchily in both the Qur'ān and the Ḥadīth (the record of the sayings attributed to the Prophet). The Qur'ān records that, when asked about these matters by local leaders of the Jewish faith, the Prophet answered that "the spirit cometh by command of God" and that "only a little knowledge was communicated to man" (17:85). Humanity was created from "potter's clay, from mud molded into shape" into which Allāh has "breathed his spirit" (15:28–29). A vital spirit or soul (*nafs*) is within each human being. It is associated, if not actually identified, with individuality and also with the seat of rational consciousness. It is interesting to speculate on the possible relation of the term *nafs* to such Arabic words as *nafas* ("breath") and *nafīs* ("precious"), particularly in a language where there are no written vowels.

Nature of the soul

Death is repeatedly compared with sleep, which is at times described as "the little death." God takes away people's souls "during their sleep" and "upon their death." He "retains those against whom he has decreed death, but returns the others to their bodies for an appointed term" (39:42–43). During death, the soul "rises into the throat" (56:83) before leaving the body. These are interesting passages in the light of modern medical knowledge. The study of sleep has identified the episodic occurrence of short periods during which the limbs are totally flaccid and without reflexes, as would be the limbs of the recently dead. Modern neurophysiology, moreover, stresses the role of structures in the upper part of the brain stem in the maintenance of the waking state. Lesions just a little higher (in the hypothalamus) cause excessively long episodes of sleep. Irreversible damage at these sites is part of the modern concept of death. Finally, various types of breathing disturbance are characteristic of brain-stem lesions and could have been attributed, in former times, to occurrences in the throat. Nothing in these passages outrages the insights of modern neurology. The absence of any cardiological dimension is striking.

Events at the moment of death

It is orthodox Muslim belief that when someone dies the Angel of Death (*malāk al-mawt*) arrives, sits at the head of the deceased, and addresses each soul according to its known status. According to the *Kitāb al-rūh,* wicked souls are instructed "to depart to the wrath of God." Fearing what awaits them, they seek refuge throughout the body and have to be extracted "like the dragging of an iron skewer through moist wool, tearing the veins and sinews." Angels place the soul in a hair cloth and "the odour from it is like the stench of a decomposing carcass." A full record is made, and the soul is then returned to the body in the grave. "Good and contented souls" are instructed "to depart to the mercy of God." They leave the body, "flowing as easily as a drop from a waterskin"; are wrapped by angels in a perfumed shroud, and are taken to the "seventh heaven," where the record is kept. These souls, too, are then returned to their bodies.

Two angels coloured blue and black, known as Munkar and Nakīr, then question the deceased about basic doctrinal tenets. In a sense this trial at the grave (*fitnat al-Qabr*) is a show trial, the verdict having already been decided. Believers hear it proclaimed by a herald, and in anticipation of the comforts of *al-jannah* (the Garden, or "paradise") their graves expand "as far as the eye can reach." Unbelievers fail the test. The herald proclaims that they are to be tormented in the grave; a door opens in their tomb to let in heat and smoke from *jihannam* ("hell"), and the tomb itself contracts "so that their ribs are piled up upon one another." The period between burial and the final judgment is known as *al-barzakh.* At the final judgment (*yaum al-Hisāb*), unbelievers and the god-fearing are alike resurrected. Both are endowed with physical bodies, with which to suffer or enjoy whatever lies in store for them. The justified enter Gardens of Delight, which are described in the Qur'ān in terms of prevalent, but essentially masculine, tastes (37:42–48). At the reception feast on the Day of Judgment unbelievers fill their bellies with bitter fruit, and "drink down upon it hot water, drinking as drinks the camel crazed with thirst" (56:52–55). They then proceed to hell, where they don "garments of fire" (22:19) and have boiling water poured over their heads. Allāh has made provision against the annihilation of the body of the damned, promising that "whenever their skins are cooked to a turn, We shall substitute new skins for them, that they may feel the punishment" (4:56). Pleas for annihilation are disregarded. Although this is sometimes referred to as the "second death," the Qur'ān is explicit that in this state the damned "neither live nor die" (87:13).

Final judgment

A special fate is reserved for the martyrs of Islām; *i.e.,* for those who fall in a *jihād* ("holy war"). Their evil deeds are instantly expiated and the formalities of judgment are waived; they enter the Garden immediately. Similar dispensations are promised to "those who had left their homes, or been driven therefrom, or who had suffered harm" in the divine cause (3:195). For the Shī'ites, followers of the smaller of Islām's two major branches, the prospects for martyrdom are even wider. A major event of the origin of Shī'ism, moreover, was the slaughter of the Prophet's grandson, Ḥusayn, in 680; this heritage has imbued Shī'ism with a zeal for martyrdom. Some of the behaviour of Islāmic fundamentalists is explicable from this perspective.

A gentler strand in Islāmic eschatology produced, over

the centuries, a series of reinterpretations or adaptations of the original doctrine, some of whose tenets were even claimed to have been only metaphorical. These tendencies, which stressed individual responsibility, were often influenced by the Ṣūfīs (Islāmic mystics).

Muslims accord a great respect to dead bodies, which have to be disposed of very promptly. The mere suggestion of cremation, however, is viewed with abhorrence. The philosophical basis, if any, of this attitude is not clear. It is not stated, for instance, that an intact body will be required at the time of resurrection. It is unlikely, moreover, that the abhorrence—which Orthodox Jews share—arose out of a desire to differentiate Islāmic practices from those of other "people of the Book" (*i.e.,* Jews and Christians). The attitude toward dead bodies has had practical consequences; for instance, in relation to medical education. It is almost impossible to carry out postmortem examinations in many Islāmic countries. Medical students in Saudi Arabia, for example, study anatomy on corpses imported from non-Islāmic countries. They learn pathology only from textbooks; many complete their medical training never having seen a real brain destroyed by a real cerebral hemorrhage.

Attitudes toward transplantation

In 1982 organ donation after death was declared *ḥallāl* ("permissible") by the Senior 'Ulamā' Commission, the highest religious authority on such matters in Saudi Arabia (and hence throughout the Islāmic world). Tales inculcated in childhood continue, however, to influence public attitudes in Islāmic nations. The widely told story of how the Prophet's uncle Ḥamzah was murdered by the heathen Hind, who then opened the murdered man's belly and chewed up his liver, has slowed public acceptance of liver transplantation. Kidney transplantation is more acceptable, perhaps because the Ḥadīth explicitly states that those entering the Garden will never more urinate.

The modern Western context. *The Christian legacy.* The spread of rationalistic and scientific ideas since the 18th century has undermined many aspects of religion, including many Christian beliefs. The church, moreover, although still seeking to exert its influence, has ceased to dominate civil life in the way it once did. Religion is no longer the pivot of all social relations as it once was in ancient Egypt and still is in some Islāmic countries. The decline of the church is epitomized by the fact that, while it is still prepared to speak of the symbolic significance of the death of Jesus Christ (and of human death in general), it has ceased to emphasize many aspects of its initial eschatology and to concern itself, as in the past, with the particular details of individual death. In the age of Hiroshima and Nagasaki, the elaborate descriptions of heaven, purgatory, and hell in Dante's *Divine Comedy,* while remaining beautiful literature, at best raise a smile if thought of as outlines for humanity's future.

The centrality of death to Christianity

Death is at the very core of the Christian religion. Not only is the cross to be found in cemeteries and places of worship alike, but the premise of the religion is that, by their own action, humans have forfeited immortality. Through abuse of the freedom granted in the Garden of Eden, Adam and Eve not only sinned and fell from grace, but they also transmitted sin to their descendants: the sins of the fathers are visited on the children. And as "the wages of sin is death" (Rom. 6:23), death became the universal fate: "Therefore as sin came into the world through one man and death through sin, and so death spread to all men" (Rom. 5:12). Christian theologians spent the best part of two millennia sorting out these implications and devising ways out of the dire prognosis implicit in the concept of original sin. The main salvation was to be baptism into the death of Jesus Christ (Rom. 6:3–4).

Among early Christians delay in the promised Second Coming of Christ led to an increasing preoccupation with what happened to the dead as they awaited the resurrection and the Last Judgment. One view was that there would be an immediate individual judgment and that instant justice would follow: the deceased would be dispatched forthwith to hell or paradise. This notion demeaned the impact of the great prophecy of a collective mass resurrection, followed by a public mass trial on a gigantic scale. Moreover, it deprived the dead of any chance of a postmortem (*i.e.,* very belated) expiation of their misdeeds. The Roman Catholic notion of purgatory sought to resolve the latter problem; regulated torture would expiate some of the sins of those not totally beyond redemption.

The second view was that the dead just slept, pending the mass resurrection. But as the sleep might last for millennia, it was felt that the heavenly gratification of the just was being arbitrarily, and somewhat unfairly, deferred. As for the wicked, they were obtaining an unwarranted respite. The Carthaginian theologian Tertullian, one of the Church Fathers, outlined the possibility of still further adjustments. In his *Adversus Marcionem,* written about 207, he described "a spatial concept that may be called Abraham's bosom for receiving the soul of all people." Although not celestial, it was "above the lower regions and would provide refreshment (*refrigerium*) to the souls of the just until the consummation of all things in the great resurrection." The Byzantine Church formally endorsed the concept, which inspired some most interesting art in both eastern and western Europe.

During its early years, the Christian Church debated death in largely religious terms. The *acerbitas mortis* ("bitterness of death") was very real, and pious deathbeds had to be fortified by the acceptance of pain as an offering to God. Life expectancy fell far short of the promised threescore years and 10. Eastern medicine remained for a long time in advance of that practiced in the West, and the church's interventions were largely spiritual. It was only during the Renaissance and the later age of Enlightenment that an intellectual shift became perceptible.

Descartes, the pineal soul, and brain-stem death. The first attempts to localize the soul go back to classical antiquity. The soul had originally been thought to reside in the liver, an organ to which no other function could, at that time, be attributed. Empedocles, Democritus, Aristotle, the Stoics, and the Epicureans had later held its abode to be the heart. Other Greeks (Pythagorus, Plato, and Galen) had opted for the brain. Herophilus (flourished *c.* 300 BC), a famous physician of the Greek medical school of Alexandria, had sought to circumscribe its habitat to the fourth ventricle of the brain; that is, to a small area immediately above the brain stem. Controversy persisted to the very end of the 16th century.

The departure of the soul from the body had always been central to the Christian concept of death. But the soul had come to mean different things to various classical and medieval thinkers. There was a "vegetative soul," responsible for what we would now call autonomic function; a "sensitive soul," responsible for what modern physiologists would describe as reflex responses to environmental stimuli; and, most importantly, a "reasoning soul," responsible for making a rational entity (*res cogitans*) of human beings. The reasoning soul was an essentially human attribute and was the basis of thought, judgment, and responsibility for one's actions. Its departure implied death. The *Anatome Corporis Humani* (1672) of Isbrand van Diemerbroeck, professor at Utrecht, appears to have been the last textbook of anatomy that discussed the soul within a routine description of human parts. Thereafter, the soul disappeared from the scope of anatomy.

Concepts of the soul

The modern and entirely secular concept of brain-stem death can, perhaps rather surprisingly, find both a conceptual and a topographical foundation in the writings of René Descartes (1596–1650), the great French philosopher and mathematician who sought to bring analytical geometry, physics, physiology, cosmology, and religion into an integrated conceptual framework. Descartes considered the body and the soul to be ontologically separate but interacting entities, each with its own particular attributes. He then sought to specify both their mode and site of interaction; the latter he deduced to be the pineal gland. The pineal was to become, in the words of Geoffrey Jefferson, "the nodal point of Cartesian dualism."

Before Descartes, the prevailing wisdom, largely derived from Greece, had regarded the soul both as the motive force of all human physiological functions and as the conscious agent of volition, cognition, and reason. Descartes succeeded in eliminating the soul's general physiological role altogether and in circumscribing its cognitive role to

the human species. Descartes's writings about death show that his concept of the soul clearly implied both mind and the immaterial principle of immortality. It had to mean both things, for no one had ever conceived of survival after death without a mind to verify the fact of continued existence, to enjoy its pleasures, and to suffer its pains.

The relation between body and soul had been discussed in patristic literature, and, because of his Jesuit education, Descartes would have been familiar with these discussions. The church's interest in these matters was strictly nonmedical, seeking only to reconcile earlier Greek theories with its own current doctrines. Descartes was the first to tackle these problems in a physiological way. With one foot still firmly on consecrated ground (and with Galileo's difficulties with the Inquisition very much in mind), he sought to give a materialistic, even mechanistic, dimension to the discussion. In this sense, his *De Homine* (*On Man*; published posthumously in 1662) can be thought of as an updating of Plato's *Timaeus.* His contemporaries viewed Descartes as having delivered the coup de grace to an earlier Greek tradition (dating back to several centuries before Christ) that had claimed that animals, as well as humans, had souls. This had been the subject of much discussion in the early Christian Church. During the 4th century, St. John Chrysostom (onetime archbishop of Constantinople) had denounced the idea, attributing it to the devil, who had allegedly managed by various maneuvers to deceive people as varied as Pythagoras, Plato, Pliny, and even Zoroaster.

Descartes probably was impressed by the central location of the unpaired pineal gland, situated where neural pathways from the retinas converge with those conveying feelings from the limbs. This "general reflector of all sorts of sensation" is, moreover, sited in the immediate proximity of the brain ventricles, from which (according to the wisdom of the day) "animal spirits" flowed into the hollow nerves, carrying instructions to the muscles. In his *Excerpta Anatomica,* Descartes had even likened the pineal to a penis obturating the passage between the third and fourth ventricles.

Descartes's ideas regarding the pineal gland

Descartes proved wrong in his beliefs that all sensory inputs focused on the pineal gland and that the pineal itself was a selective motor organ, suspended in a whirl of "animal spirits," dancing and jigging "like a balloon captive above a fire," yet capable in humans of scrutinizing inputs and producing actions "consistent with wisdom." He was also wrong when he spoke of the "ideas formed on the surface" of the pineal gland, and in his attribution to the pineal of such functions as "volition, cognition, memory, imagination, and reason." But he was uncannily correct in his insight that a very small part of this deep and central area of the brain was relevant to some of the functions he stressed. We now know that immediately below the pineal gland there lies the mesencephalic tegmentum (the uppermost part of the brain stem), which is crucial to generating alertness (the capacity for consciousness), without which, of course, there can be no volition, cognition, or reason.

It is a matter of vocabulary whether one considers the mesencephalic tegmentum either as being involved in generating a "capacity for consciousness" or as preparing the brain for the exercise of what Descartes would have considered the "functions of the soul" (volition, cognition, and reason). In either case, the total and irreversible loss of these functions dramatically alters the ontological status of the subject. Descartes specifically considered the example of death. In "La Description du corps humain" (1664) he wrote that "although movements cease in the body when it is dead and the soul departs, one cannot deduce from these facts that the soul produced the movements." In a formulation of really modern tenor, he then added "one can only infer that the same single cause (a) renders the body incapable of movement and (b) causes the soul to absent itself." He did not, of course, say that this "same single cause" was the death of the brain stem. Some 300 years later, in 1968, the Harvard Committee spoke of death in terms of "irreversible coma" (where Descartes had spoken of the "now absent soul") and stressed, as had Descartes, the immobility of the comatose body. The religious and secular terms seem to describe the same reality.

There have been other neurological controversies concerning the locus of the soul. Early in the 18th century Stephen Hales, an English clergyman with a great interest in science, repeated an experiment originally reported by Leonardo da Vinci. Hales tied a ligature around the neck of a frog and cut off its head. The heart continued to beat for a while, as it usually does in the brain dead. Thirty hours later, the limbs of the animal still withdrew when stimulated. In fact, the elicited movements only ceased when the spinal cord itself had been destroyed. This observation gave rise to a great controversy. Reflex action at spinal cord level was not then fully understood, and it was argued that the irritability implied sentience, and that sentience suggested that the soul was still present. The "spinal cord soul" became the subject of much debate. It is now known that such purely spinal reflex movements may occur below a dead brain. It was shown during the 19th century that individuals executed on the guillotine might retain the knee jerk reflex for up to 20 minutes after decapitation.

Modern theological concerns

The church is still concerned with the diagnosis of death, but the theological argument has, during the last half of the 20th century, moved to an entirely different plane. As mentioned earlier, in 1957 Pope Pius XII raised the question whether, in intensive care units, doctors might be "continuing the resuscitation process, despite the fact that the soul may already have left the body." He even asked one of the central questions confronting modern medicine, namely whether "death had already occurred after grave trauma to the brain, which has provoked deep unconsciousness and central breathing paralysis, the fatal consequences of which have been retarded by artificial respiration." The answer, he said, "did not fall within the competence of the Church."

Public attitudes. Until about 100 years ago, people had by and large come to terms with death. They usually died in their homes, among their relatives. In villages, in the 18th or early 19th centuries, passers-by might join the priest bearing the last sacrament on his visit to the dying man or woman. Doctors even stressed the public health hazards this might cause. Numerous pictures attest to the fact that children were not excluded from deathbeds, as they were to be during the 20th century.

Changing attitudes toward death

The general acceptance of death was to be subverted by the advances of modern medicine and by the rapid spread of rationalist thought. This led, during a period of only a few decades, to a striking change of attitudes. In the advanced industrial countries, a large number of people now die in hospitals. The improvement in life expectancy and the advances of modern surgery and medicine have been achieved at a certain price. A mechanistic approach has developed, in which the protraction of dying has become a major by-product of modern technology. The philosophy of modern medicine has been diverted from attention to the sick and has begun to reify the sickness. Instead of perceiving death as something natural, modern physicians have come to see it as bad or alien, a defeat of all their therapeutic endeavours, at times almost as a personal defeat. Sickness is treated with all possible weapons, often without sufficient thought for the sick person—at times even without thought as to whether there is still a "person" at all. The capacity to "care" for biological preparations, with no other human attribute than physical form, is part of the context in which the reevaluation of death described earlier has taken place.

Parallel developments have taken place at the level of the psyche of the dying person and of the person's relatives. Elisabeth Kübler-Ross, an American psychiatrist, has outlined the stages (denial, anger, bargaining, preparatory grief, and acceptance) through which people, informed of their own approaching death, are said to pass. Her writings are based on a wide but essentially American experience, and their universality has not been tested, particularly in other cultural contexts. They may well prove somewhat ethnocentric.

The development of the death industry (satirized in Evelyn Waugh's *Loved One* and explored in Jessica Mitford's *American Way of Death*) is also a by-product of the technological revolution and of modern attitudes to

death. Undertakers have become "morticians" and coffins "caskets." Embalming has enjoyed a new vogue. Drive-in cemeteries have appeared, for those seeking to reconcile devotion to the dead with other pressing engagements. Cryogenic storage of the corpse has been offered as a means to preserve the deceased in a form amendable to any future therapies that science may devise. Commercial concerns have entered the scene: nonpayment of maintenance charges may result in threats of thawing and putrefaction. In a contentious environment, the law has even invaded the intensive care unit, influencing the decisions of physicians concerning the withdrawal of treatment or the determination of death. A wit has remarked that in the modern era, the only sure sign that a man is dead is that he is no longer capable of litigation.

BIBLIOGRAPHY

Biological aspects: The concept of apoptosis (programmed cell death) is outlined in A. GLÜCKSMAN, "Cell Deaths in Normal Vertebrate Ontogeny," *Biological Reviews of the Cambridge Philosophical Society,* 26:59–86 (1951); A.H. WYLLIE, J.F.R. KERR, and A.R. CURRIE, "Cell Death: The Significance of Apoptosis," *International Review of Cytology,* 68:251–306 (1980); I.D. BOWEN and R.A. LOCKSHIN (eds.), *Cell Death in Biology and Pathology* (1981); I. DAVIES and D.C. SIGEE (eds.), *Cell Ageing and Cell Death* (1985). The development of the idea of brain death (and of its evolution into the concept of brain-stem death) can be followed in P. MOLLARET and M. GOULON, "Le Coma dépassé," *Revue Neurologique,* 101(1):3–15 (July 1959); AD HOC COMMITTEE OF THE HARVARD MEDICAL SCHOOL TO EXAMINE THE DEFINITION OF BRAIN DEATH, "A Definition of Irreversible Coma," *J.A.M.A.,* 205(6):337–340 (Aug. 5, 1968); JULIUS KOREIN (ed.), *Brain Death: Interrelated Medical and Social Issues* (1978); A. BERNAT, "The Definition, Criterion, and Statute of Death," *Seminars in Neurology,* 4(1):45–51 (March 1984).

Philosophical and cultural aspects: E.A. WALLIS BUDGE, *Egyptian Ideas of the Future Life: Egyptian Religion* (1899, reprinted 1979 as *Egyptian Religion: Egyptian Ideas of the Future Life*); ANGE P. LECA, *La Médecine égyptienne au temps des pharaons* (1971); ALEXANDRE PIANKOFF (ed.), *Le "Cœur" dans les textes égyptiens depuis l'ancien jusqu' à la fin du nouvel empire* (1930); and HENRY E. SIGERIST, *A History of Medicine,* 2 vol. (1951–61), are useful reviews of the notion of death in ancient Egypt. Mesopotamian concepts are described in J. HACKIN *et. al., Asiatic Mythology* (1932, reissued 1963); and SAMUEL GEORGE FREDERICK BRANDON, *Man and His Destiny in the Great Religions* (1962, reprinted 1963). The latter and F.H. GARRISON, "The Bone Called 'Luz,'" *New York Medical Journal,* 92(4):149–151 (July 23, 1910), also contain much useful information on Judaic attitudes. Hindu perceptions and practices are detailed in PAUL THOMAS, *Hindu Religion, Customs and Manners,* 6th ed. (1975); and NIRAD C. CHAUDHURI, *Hinduism: A Religion to Live By* (1979, reprinted 1980). MUḤAMMAD IBN ABĪ-BAKR IBN QAYYIM AL-JAWZĪYAH, *Kitāb al-rūḥ,* 2nd ed. (1324); and FRANK E. REYNOLDS and EARLE H. WAUGH (eds.), *Religious Encounters with Death: Insights from the History and Anthropology of Religions* (1977), present Islāmic attitudes. More recent developments are discussed in T.S.R. BOASE, *Death in the Middle Ages: Mortality, Judgment and Remembrance* (1972); and PHILIPPE ARIÈS, *Western Attitudes Toward Death: From the Middle Ages to the Present,* translated from the French (1974, reprinted 1975), and *The Hour of Our Death* (1981, reissued 1982; originally published in French, 1977). Information about the "pineal soul" is found in RENÉ DESCARTES, *Treatise of Man,* translated from the 1664 French edition, by THOMAS STEELE HALL (1972), originally published in a Latin translation, 1662; and about the "spinal cord soul" in EDWARD GEORGE TANDY LIDDELL, *The Discovery of Reflexes* (1960). See also GEOFFREY JEFFERSON, "René Descartes on the Localisation of the Soul," *Irish Journal of Medical Science,* 285:691–706 (Sept. 1949); and G. CORNER, "Anatomists in Search of the Soul," *Annals of Medical History,* 2(1):1–7 (Spring 1919). Modern attitudes on death form the basis of JESSICA MITFORD, *The American Way of Death* (1963, reprinted 1978); ELISABETH KÜBLER-ROSS, *On Death and Dying* (1969, reprinted 1979); and ROBERT M. VEATCH, *Death, Dying and the Biological Revolution: Our Last Quest for Responsibility* (1976). HERMAN FEIFEL (ed.), *The Meaning of Death* (1959, reissued 1965); and JAMES P. CARSE, *Death and Existence: A Conceptual History of Human Mortality* (1980), both present excellent overviews.
